Nonrhoticity in American English originally reflected the accents of some of the early settlers from the British Isles. Recent changes, including the movement of large numbers of southern nonrhotic speakers to cities in rhotic areas, have meant that non-rhoticity is not only a geographical variable but also reflects ethnicity and class. Nonrhoticity in some urban settings is characteristic of speakers of African–American vernacular English (AAVE), and there, rhoticity can act as a socioeconomic marker, but unlike the United Kingdom, where nonrhotic speech is associated with prestigious varieties. Within the African–American community of Detroit, (R) exhibits gradual stratification, so that while only about 20 percent of upper middle-class speakers are nonrhotic, this figure climbs to approximately 70 percent for the lower working class, in a linear manner.

In New York, the social meaning of rhoticity has shifted in the previous half-century. Older speakers exhibit little class-based stratification, but younger speakers identify rhotic speech as more prestigious than nonrhotic speech. This is the converse of the British situation (at least, the English situation) as well as the converse of Southern Hemisphere varieties (Gordon *et al.*, 2004). So, nonrhoticity in the United States is beginning to be associated with rural and lower-class speech. This does not mean there are not pockets of prestigious nonrhoticity in the United States, and indeed specific locations have older upper-class nonrhotic speakers. The New York adoption and then loss of nonrhoticity as a prestige form are both, as it happens, 'change from above,' though separated by a couple of centuries and with reference to different prestige dialects: nonrhotic British English and rhotic American English, respectively. The Irish English of Dublin shows a similar pattern, in which the local vernacular is weakly rhotic but middle-class speech is strongly rhotic (Hickey, 1999).

In Philadelphia (Labov, 2001), the ethnic distribution of rhoticity is also finely drawn. Nonrhotic speech is characteristic of the African–American population (about 40% of the population), but it also appears to have been an indicator of Italian ethnicity, an effect that is in decline in apparent time. Unstressed (R) can often be nonrhotic across Italian and non-Italian communities, whereas in stressed syllables, the distribution of nonrhoticity is more complex, being more ethnically determined and prevalent in older speakers.

Finally, rhotic accents acquire extra /r/ in contact with nonrhotic varieties. Thus words such as 'theater' and 'idea' can contain an /r/ in rhotic varieties like Scottish English, since speakers interpret the [iɔ] diphthong as corresponding to /ir/, and weak final syllables that are subject to /r/ sandhi can be reinterpreted as involving an /r/ (hence 'feller' versus 'fellow'). These forms are generally lexical oddities, but their use is likely to be sociolinguistically distributed.

In general, then, it seems that vernacular or nonstandard varieties of English in the United Kingdom are driving more variation and change in a number of variables, including (R), than the prestige varieties of Scotland and England. Urban vernacular forms seem to be either on parallel paths of internal change, or influencing each other, to the extent of substantial change – even vocalization – of /r/ appearing in younger working-class speakers in the largest city in Scotland in remarkably large numbers.

Donald Davidson's idea of **radical interpretation** gets its inspiration from W. V. Quine's account of **radical translation**. This article will deal first with Quine's view and then Davidson's before turning to the **interpretationalism** of Davidson's views and criticisms of thereof.

Radical Translation

W. V. Quine is generally suspicious of such mental notions as belief, intention, and meaning, preferring an austere behaviorist account of language use. Quine imagines a field linguist attempting to compile a **translation manual** that would pair sentences of her own language with sentences of a language wholly unlike any she has ever encountered, unaided by dictionaries or local interpreters. In this scenario of **radical translation**, the linguist has access only to the bodily behavior of the speaker and to those objects and events that are manifest in the local environment. The best pragmatic procedure for the radical translator to follow, thinks Quine, is to try to correlate the speaker's utterances with their proximal stimuli – "surface irritations" (Quine, 1960: 22) of sensory receptors. If a given stimulus–say, that produced by a rabbit–can be correlated with a given utterance on one occasion – say, 'Gavagai!' – then the translator must try to reproduce similar stimuli in order to see whether they provoke similar utterances (find some more rabbits and point them out). Or, better, the translator may on various stimulus-occasions, similar and different, repeat the speaker's original utterance in the hope of eliciting terms for assent and dissent (point to

Radical Interpretation, Translation and Interpretationalism

M Hymers, Dalhousie University, Halifax, Nova Scotia, Canada

© 2006 Elsevier Ltd. All rights reserved.

Donald Davidson's idea of **radical interpretation** gets its inspiration from W. V. Quine's account of **radical translation**. This article will deal first with Quine's view and then Davidson's before turning to the **interpretationalism** of Davidson's views and criticisms of thereof.

Radical Translation

W. V. Quine is generally suspicious of such mental notions as belief, intention, and meaning, preferring an austere behaviorist account of language use. Quine imagines a field linguist attempting to compile a **translation manual** that would pair sentences of her own language with sentences of a language wholly unlike any she has ever encountered, unaided by dictionaries or local interpreters. In this scenario of **radical translation**, the linguist has access only to the bodily behavior of the speaker and to those objects and events that are manifest in the local environment. The best pragmatic procedure for the radical translator to follow, thinks Quine, is to try to correlate the speaker's utterances with their proximal stimuli – "surface irritations" (Quine, 1960: 22) of sensory receptors. If a given stimulus–say, that produced by a rabbit–can be correlated with a given utterance on one occasion – say, 'Gavagai!' – then the translator must try to reproduce similar stimuli in order to see whether they provoke similar utterances (find some more rabbits and point them out). Or, better, the translator may on various stimulus-occasions, similar and different, repeat the speaker's original utterance in the hope of eliciting terms for assent and dissent (point to

rabbits and rutabagas alike, asking, 'Gavagai?'). With a firm working hypothesis about these terms in hand, she may proceed to pair sentences of the speaker's language with sentences of her own language, according as they seem from her perspective to have the same **stimulus meanings** – that is, roughly, to be prompted by the same sorts of events and objects. Hypotheses concerning assent and dissent may, of course, meet with disconfirming evidence, forcing the translator to begin anew with another hypothesis. But by following this procedure, Quine thinks, the field linguist can expect eventually to translate **observation-statements** – reports on observable occurrent events or states of affairs. By applying a **principle of charity**, which counsels the translator not to assume wanton irrationality on the speaker's part, she may also hope to translate logical terms, such as 'not,' 'and,' and 'or,' since a rational speaker is unlikely to affirm each conjunct of a conjunction ('Roses are red' and 'Violets are blue') without also affirming the conjunction ('Roses are red, **and** violets are blue'). Efforts to take radical translation further to relatively nonobservational sentences – such as 'Electrons have negative charge' or 'Incest is an abomination' – will rely on the formulation of **analytical hypotheses** regarding how to parse the speaker's utterances into words and other subsentential components. However, Quine contends, there will always be rival systems of analytical hypotheses, any of which will be as pragmatically successful as the other for purposes of compiling a workable translation manual. Translation is thus indeterminate, but Quine thinks that the lessons of radical translation apply with equal justice to our attempts to converse with our colinguists and to our learning of our own language. Having learned the language already, we find the procedure of interpreting our fellow speakers and ourselves as familiar as can be, but in neither case do we have any more evidence to go on than is available to the field linguist. It follows, thinks Quine, that meaning itself is no more determinate than translation (*see* **Indeterminacy, Semantic**).

Radical Interpretation

In the work of Donald Davidson, radical translation is transmuted into **radical interpretation**. The two notions differ in at least three important respects. (1) Whereas the former notion rests on methodological behaviorism, the latter does not. (2) Whereas radical translation aims to compile a translation manual for the language under study, radical interpretation aims to formulate and test, as part of a general theory of interpretation for a speaker, a core meaning theory for the speaker's language, which will describe the finite vocabulary of the language and show how that vocabulary can be combined using a finite set of recursive rules to produce any sentence in the language. Knowledge of such a theory would supposedly "suffice" (Davidson, 1984: 172; 1986: 438) for understanding the speaker, but is not necessary (1984: 125; 1986: 438). (3) Whereas radical translation relies on the principle of charity methodologically to argue for the translatability of logical connectives, radical interpretation applies this principle generally as something like a necessary condition of the very possibility of interpretation (Ramberg, 1989: 77). These points need elaboration.

(1) Quine focuses on terms for assent or dissent "because they suggest a behaviouristic test," but Davidson has no such commitment to behaviorism (Davidson, 1984: 231). He criticizes Quine's preoccupation with proximal causes of sensory stimulation, arguing that Quine slips back into a Cartesian model of the mind as isolated from the world, thereby exposing himself to both an "old-fashioned skepticism of the senses" (Davidson, 1990: 74) and a relativism about truth that arises from the fact that no two individuals share the same patterns of sensory stimulation (1990: 76). Translation even of observation sentences, which Davidson does not distinguish sharply from theoretical sentences (2001: 149) can be assured to work only if the interpreter focuses on macroscopic objects and events in a world shared by interpreter and speaker – marmots and mangoes, instead of photons striking nerve endings. In order to locate the source of the speaker's sensory stimulations, we need, says Davidson, three patterns of similarity from one occasion to another: the similarity I find in my experiences, the similarity the speaker finds in her experiences, and the similarity that I find in the speaker's responses to her experiences (2001: 119). The interpreter must "correlate his own responses and those of the speaker by reference to the mutually salient causes in the world of which they speak" (1990: 78) – a process Davidson analogizes to '**triangulation**' (2001: 105). (See 'Interpretationalism' below for more on this process.)

(2) The notion of translation does not by itself, thinks Davidson, give a plausible account of meaning for the speaker's language. A better account would have to show systematically how "the meanings of sentences depend upon the meanings of words" (2001: 17) if a speaker's capacity to understand and produce a potential infinity of novel and banal utterances is to be represented (*see* **Compositionality: Philosophical Aspects**). Drawing on the formal logical work of Alfred Tarski (1949), Davidson proposes that we begin the task of interpretation by taking as basic the attitude of holding a sentence true (or false). Then, having identified the sentences a speaker holds

true, we must formulate hypotheses about what finite vocabulary and what rules of syntax are operating in the speaker's language, and what rules of satisfaction are descriptive of the various predicates in the language. (A rule of satisfaction tells us what things satisfy a given predicate – roughly, of what things that predicate is true. It tells us which are the blue things or the koalas, for example.) Such a procedure provides a "model" (Davidson, 1986: 438) of what we commonly do when interpreting a speaker, though we cannot be plausibly said to **know** any such theory of interpretation (1986: 438). What exactly this means has occasioned some puzzlement (see Dummett, 1975, 1976; Schiffer, 1989: 116–117).

(3) This procedure requires that we be able to identify which sentences a speaker holds true, but this by itself will not tell us what those sentences mean. If we knew what the speaker believed in the circumstances, then that would give us some substantial clues concerning what she means by her sentences. However, our surest way of identifying what a speaker believes is by first knowing what her words mean. To escape this endless circle, Davidson appeals to the principle of charity, which, in his formulation, has it that we should "assume general agreement on beliefs" (1984: 196) and "try for a theory that finds [the speaker] consistent, a believer of truths, and a lover of the good (all by our own lights, it goes without saying)" (1980: 222). This is not a principle that we choose simply in order to avoid making our speaker sound "silly" (Quine, 1960: 59). Rather, "charity is forced on us" (Davidson, 1984: 197) if we are to be in a position to interpret our speaker **at all**.

Davidson believes that meaning- and attitude-attribution are holistic by nature. There is no sense to the idea of attributing a belief to a creature unless one attributes "a world of further beliefs to give it content and identity" (Davidson, 2001: 98) and likewise no way of assigning meaning to a sentence in isolation from assignments of meaning to other sentences (1980: 239). Such holism entails the possibility of reassigning meaning and content, so long as one makes compensating adjustments elsewhere in the attributed set of background meanings and beliefs. Thus Davidson allows for an indeterminacy of interpretation that is the "semantic analogue of Quine's indeterminacy of translation" (1984: 225), but as a consequence of his broader application of the principle of charity, he believes that "the range of indeterminacy is less than Quine thinks it is" (1984: 228). What indeterminacy remains is, in Davidson's view, comparable to the possibility of adopting different scales of measurement for the same objective phenomenon, much as we may measure temperature on the Fahrenheit or Celsius scales (1984: 154, 225; 1980: 257; 2001: 145). Additionally, Davidson regards it as a facet of linguistic competence that one has "first person authority" (2001: 3) concerning the meanings of one's own words and the contents of one's own thoughts. So, unlike Quine, he does not think radical interpretation "begins at home" (Quine, 1969: 46) (though it might begin next door when one interprets one's colinguists).

Interpretationalism

Davidson's account of radical interpretation is readily coupled to a view about meaning and intentional content known as **interpretationalism**. Much as Quine maintains that translation is prior to meaning and not vice versa, as we might have thought prereflectively, Davidson contends that there is no fact concerning what a speaker's words mean or what the contents of her intentional attitudes are apart from the possibility of their meaning or content being attributed by an interpreter. This is because, as we saw briefly above, interpreting a speaker requires identifying the mutually salient causes of her verbal behavior. Any link in the causal chain extending from a publicly observable object to the surface irritations of her sensory organs could, on some account, be identified as the cause if the speaker is left to try to interpret herself. From a third-person point of view, however, what seems explanatory of the speaker's behavior is her pattern of responses to public objects, to which we also respond. "It takes two points of view to give a location to the cause of a thought, and thus to define its content" (Davidson, 2001: 212–213).

Criticisms of Radical Interpretation and Interpretationalism

Critics of interpretationalism may accuse it of an implausible instrumentalism about the mental (Davidson, 2001: 70; Hookway, 1988: 181), according to which intentional attitudes are no more than convenient fictions that we employ when trying to predict and explain the behavior of a rational creature. Furthermore, interpretationalism seems to lead to a vicious regress, since one's possession of meanings and intentional attitudes requires being interpreted by another, whose intentional attitudes, in turn, must be derived from the interpretations of a third, and so on (Heil, 1998: 131). Similar criticisms are made of Daniel Dennett's "intentional stance" (1971; 1987) – see Putnam, 1987: 15–16; Rudder-Baker, 1989: 305 – a variety of "selective instrumentalism" (Dennett, 1987: 72), which Dennett distinguishes from "interpretationism" (1987: 15) and "classical

instrumentalism" (1987: 71). Davidson (2001: 82) thinks that Dennett confuses the question of whether intentional attitudes are entities with the question of whether there are correct answers about what intentional attitudes anyone has. But Davidson replies here that his account is no more instrumentalist than are systems of measurement (2001: 74–75). The fact that we can measure temperature differently in Fahrenheit or Celsius does not show that no objective phenomenon is being measured; Dennett makes a similar response to the parallel criticism of his view (1987: 34). And the apparent regress arises only if we fail to see practices of interpretation as coming into being gradually and socially, producing interpretative communities "once they reach an appropriate level of sophistication" (Heil, 1998: 153).

Critics have doubted Davidson's ability to account for the meanings of sentences that, intuitively, are neither true nor false, such as interrogatives and imperatives, and, perhaps more seriously, of such sentences as direct and indirect quotations and attributions of intentional attitudes. (Tarski himself thought that his treatment of truth, from which Davidson borrows, could not be applied to natural languages.) Davidson has long recognized that there are programmatic challenges of this sort for his view to meet (1984: 35–36) and has taken an optimistic view of his chances, viewing the problems as a series of puzzles to be dealt with by an active research program (see the various essays in Davidson, 1984), though many critics remain pessimistic (Glock, 2003: 159–165; Schiffer, 1989).

Davidson's use of the principle of charity has also been criticized on a number of grounds. Some think it smacks of cultural imperialism, forcing us to construe cultural others as like their interpreters in all essential respects (MacIntyre, 1985). Davidson may respond that meaningful disagreement requires a broad background of agreement and that cultural difference cannot even be recognized without starting with something like the principle of charity (1984: 196–197; 2001: 39–41, 148–149). Some critics have suggested that charity is not sufficient for interpretation, since we have reason not to attribute what we take to be true beliefs to a speaker if it would be mysterious how she came to hold such a belief (Grandy, 1973: 445), and have proposed in its place a "principle of humanity" (Grandy, 1973: 443) according to which we should attribute beliefs that we would find it reasonable to hold in the speaker's position. Davidson has responded with attempts to clarify the principle of charity (1984: xvii, 136) and with a proposal to distinguish two principles, Coherence and Correspondence (2001: 211). Others contend that it is shared behavior, not merely agreement in beliefs, that makes interpretation possible and that successful interpretation can thus succeed in the absence of charity (Glock, 2003: 194–199), but although such behavioral commonality may not be premised in the principle of charity, Davidson seems to agree that it is of central importance (2001: 128–129, 212–213), and the difference here is **perhaps** one of emphasis.

Radio: Language

R Fitzgerald, University of Queensland, Brisbane, Australia

© 2006 Elsevier Ltd. All rights reserved.

Radio is one of the most accessible, most flexible, and cheapest forms of mass communication, providing entertainment and news to millions of people all over the world primarily through the broadcast voice. Voice or talk introduces, describes, and fills in between music tracks while on talk radio the broadcast is dominated by continuous talk: chatter, interviews, gossip, public information, news, sport, education, drama, and comedy. Because of the dominance of the voice and the wide variety of uses for which the medium is employed, radio provides an important area for language analysis, particularly in those areas that give primacy to the social and political context of language use and its discursive organization, i.e., sociolinguistics, pragmatics, (critical) discourse analysis, and conversation analysis. For these areas of research radio language provides the raw materials with which to explore the linguistic and discursive methods of communicative competence and meaning production for a mass overhearing, and largely remote, audience, as well as the dynamics of interpersonal interaction within the intersection between public and private realms of communication.

One of the most interesting things about radio is that, although produced for a remote mass overhearing audience, the language is oriented toward creating a sense of intimacy between the presenter and listener. The disembodied remote talk, promiscuously broadcast to anyone with a radio, attempts to generate both the sense that the listener is being addressed directly by the presenter and also that the listener is part of a listening community. Indeed the radio is often perceived as being a 'friend' with the voice giving comfort, company, and even hope. This sense of intimacy and informality is generated through linguistic forms and as such offers a rich resource by which to examine not only the way language is used as mass communication, but also the way it generates and sustains the uniqueness of the medium (Bell, 1991).

Speak Easy

While there are similarities between television and radio, such that both are designed for a mass overhearing audience and both must attend to the diversity of the potential audience, unlike television or indeed the Internet, radio is a purely aural medium where no visual cues and codes are available and where the voice or sound must carry all the information that is to be conveyed. In the early days of radio, emphasis was necessarily given to clarity of voice, given the relatively crude technology. With improvements in technology and the growing awareness of a diverse audience, an informal conversational style, more like chat or gossip (Coupland, 2001), was incorporated into newer stations, especially after the launch of pirate stations such as Radio Caroline. However, while speech styles on radio may occupy different positions displaying both formal and informal codes, interestingly, the most informal style of speaking still contains many formal characteristics. The most casual of talk on radio, e.g., the music DJ or magazine program chat, is noticeably more fluent, precise, and orderly than ordinary spontaneous speech encounters and is also run to a precise time while covering the information deemed necessary for that broadcast. Because of the apparent 'restriction' of radio to sound, more emphasis is given to clarity of expression, delivery, and style of address, and, according to Crisell (1994), this style draws upon a combination of both oral and literary linguistic codes. Although the oral tradition on radio is very strong in that it relies upon being heard rather than seen, the fact that radio output is largely scripted and therefore premeditated lends itself to literary codes that involve thinking out the language, structure, and direction before delivery. As Ervin Goffman, one of the pioneers in the study of radio language, points out,

Radio is one of the most accessible, most flexible, and cheapest forms of mass communication, providing entertainment and news to millions of people all over the world primarily through the broadcast voice. Voice or talk introduces, describes, and fills in between music tracks while on talk radio the broadcast is dominated by continuous talk: chatter, interviews, gossip, public information, news, sport, education, drama, and comedy. Because of the dominance of the voice and the wide variety of uses for which the medium is employed, radio provides an important area for language analysis, particularly in those areas that give primacy to the social and political context of language use and its discursive organization, i.e., sociolinguistics, pragmatics, (critical) discourse analysis, and conversation analysis. For these areas of research radio language provides the raw materials with which to explore the linguistic and discursive methods of communicative competence and meaning production for a mass overhearing, and largely remote, audience, as well as the dynamics of interpersonal interaction within the intersection between public and private realms of communication.

One of the most interesting things about radio is that, although produced for a remote mass overhearing audience, the language is oriented toward creating a sense of intimacy between the presenter and listener. The disembodied remote talk, promiscuously broadcast to anyone with a radio, attempts to generate both the sense that the listener is being addressed directly by the presenter and also that the listener is part of a listening community. Indeed the radio is often perceived as being a 'friend' with the voice giving comfort, company, and even hope. This sense of intimacy and informality is generated through linguistic forms and as such offers a rich resource by which to examine not only the way language is used as mass communication, but also the way it generates and sustains the uniqueness of the medium (Bell, 1991).

Speak Easy

While there are similarities between television and radio, such that both are designed for a mass overhearing audience and both must attend to the diversity of the potential audience, unlike television or indeed the Internet, radio is a purely aural medium where no visual cues and codes are available and where the voice or sound must carry all the information that is to be conveyed. In the early days of radio, emphasis was necessarily given to clarity of voice, given the relatively crude technology. With improvements in technology and the growing awareness of a diverse audience, an informal conversational style, more like chat or gossip (Coupland, 2001), was incorporated into newer stations, especially after the launch of pirate stations such as Radio Caroline. However, while speech styles on radio may occupy different positions displaying both formal and informal codes, interestingly, the most informal style of speaking still contains many formal characteristics. The most casual of talk on radio, e.g., the music DJ or magazine program chat, is noticeably more fluent, precise, and orderly than ordinary spontaneous speech encounters and is also run to a precise time while covering the information deemed necessary for that broadcast. Because of the apparent 'restriction' of radio to sound, more emphasis is given to clarity of expression, delivery, and style of address, and, according to Crisell (1994), this style draws upon a combination of both oral and literary linguistic codes. Although the oral tradition on radio is very strong in that it relies upon being heard rather than seen, the fact that radio output is largely scripted and therefore premeditated lends itself to literary codes that involve thinking out the language, structure, and direction before delivery. As Ervin Goffman, one of the pioneers in the study of radio language, points out,

> although ordinary talk is full of technical faults that go unnoticed as faults, broadcasters seem to be schooled to realize our cultural stereotypes about speech production, namely, that ordinarily it will be without influences, slips, boners, and gaffes i.e., unfaultable. (Goffman, 1981: 240)

While the fluency and precision of radio broadcasting emanates from the largely scripted nature of the talk, there is also an orientation to animate or personalize many of the scripts and thereby hide the preprepared text while delivering it in a style that is seemingly spontaneous (Goffman, 1981; Scannell, 1996; Crisell, 1994).

Scripted Spontaneity

In the early days of radio it was relatively easy to identify radio language as scripted by the measured tone and formal style; today, however, radio is much more diverse in types of delivery (Crisell, 1994). Between the many various programs there are gradations of script and spontaneity from talk that is presented as fully scripted, for example, 'program announcing' or 'newsreading,' through scripted talk designed to appear unscripted, for example, drama, to talk that is largely unscripted except for running order and time schedule, such as radio phone-in programs or DJ talk. Because there are no visual cues or clues available for the listener to discern when a script is being used or what type of script is being delivered, there are often noticeable verbal signals that work to separate or mark out that what is coming next is to be heard as scripted speech. An upcoming news program, for example, will often be preannounced, "and now the news read by . . ." or "the news today is read by . . . ." This preannouncing not only separates the news from the previous program but also indicates that the news is different from the previous program. The news bulletin employs a more formal style than the speech that surrounds it and this also indicates that the words spoken, the content of the script, are not the words of the speaker but of the news department or news organization. By separating the news bulletin from the rest of the programme and by hearably 'reading' the script the news is presented as fact without journalist interpretation and so able to resist routine accusations of bias directed at prominent news and current affairs programmes. In other types of programming, such as community broadcasting or local radio, the presenter may work to hide the presence of a script by including ad-libs, comments aside or (deliberately) making mistakes with the equipment to 'highlight' their being amateur and incapable of even following 'the' script. Thus while the newsreader works to distance him or herself from the words spoken through a neutral and even delivery, the use of extemporaneous comments, ad-libs, and asides serve to locate the talk not only as spontaneous, as 'live,' but as the presenter's own words (Goffman, 1981). The premeditation of the script then belies the apparent spontaneity of delivery, serving to hide the linguistic work of the DJ, whose professionalism is to sound ordinary to the listeners.

Of course language, specially through talk and banter, is important to individual presenters in order to create a sense of intimacy, spontaneity, and in the end personality, but a further significant aspect is in developing a style or voice which identifies or fits in with the general character of the radio station. Martin Shingler and Cindy Wieringa suggested that

> whilst each programme will obviously require a different mode of speech – different in terms of tone, pitch, pace and accent – the station will aim to establish an overall mode of speaking to which all its presenters will, to a greater or lesser extent, conform whilst broadcasting on that station. (Shingler and Wieringa, 1998: 33)

Although a definitive 'radio voice' is not identifiable or even desirable, individual stations work to promote a particular and predictable style of speech code by which they can be identified. While the parameters of a particular station's speech character may include RP, regional, and even international voices the range within those styles will also include informal, authoritative, preachy, humorous, subversive, gossipy styles and a huge range in between (Shingler and Wieringa, 1998).

Mass Media and Intimacy of Radio Language

Because of the diverse range of speech styles, with the predominant being scripted informality, radio creates an enigma for questions concerning the nature of institutional power and how institutions define themselves through language. The fact that the language of radio is largely informal would seem to indicate an inherent contradiction between the style of radio and the institutional situation from which the speech emanates. The radio broadcast originates from one place, is delivered to a remote other and is designed for a mass overhearing audience, thus placing it within the institutional communicative framework (Scannell, 1996). However, the language, speech, and talk would seem to be designed around a direct intimate code of address usually found in copresent 'ordinary' or mundane interaction. Thus the voice of radio, the defining feature of the institution, is a contrived display of ordinary intimate conversation. Hutchby (1996) identified this

paradoxical linguistic feature within the interplay between host and caller on radio phone-ins as 'intermediate talk,' suggesting that the phone-in works at the intersection between the institution and public discourse, while Shingler and Wieringa (1998) proposed that the term can be applied more broadly to the character of most radio speech, in that it is institutional but more often sounds mundane. For Scannell (1996) this trend towards a conversational style was the logical evolution of a medium beginning to understand its audience, while for Fairclough (1998) the 'conversationalization' of media language involves a pseudoinformality and synthetic personality deliberately hiding the ideological power of the institution.

While it is clear that radio includes an eclectic and diverse combination of styles and voices, studies of radio language tend to fall into a number of major areas centered around programs such as phone-ins, DJ talk, drama and comedy, and news and current affairs. Not only does research in these broader categories provide insight into language use and style but specific areas of research are also able to explore the social and political organization of media language. Radio phone-ins, for example, can be used to highlight the tension between institutional discourse and ordinary conversation by raising questions around the role of public-access media, especially how entertainment is generated and political and institutional power exercised through language. The tension between public and private discourses is also found in the pseudosynthetic personality of the music DJ ad-libbing from the script to create or foster a more personal relationship with the listener. The linguistic codes and potential of the blind medium are explored in studies of drama and comedy where non-visual imagination is capitalized upon within the boundaries of a particular station's language policy. In discussions of news broadcasting the line between editorial comment and the trusted voice of authority for news broadcasts is part of the continual debate over what type of voice is suited to newsreading, whether it should be male or female, regional or international, etc., and also the unique strengths radio has developed upon in order to remain a viable news service in the face of television and the Internet.

Radio Drama and Comedy

Although it may seem an inherent limitation of the medium, the production of drama, serials, adaptations of classic books, and even light entertainment and comedy are some of the best things radio does. On the one hand the low production costs of radio means it is suited to experimentation and the commissioning of new talent, but on the other, the lack of a visual environment has meant that drama and light entertainment have become adept at using the medium to its best effect. Writers and producers working within the confines of the medium incorporate a number of features around what Crisell (1994: 146) referred to as 'transcodification,' replacing one set of visual codes with auditory ones. Whereas in visually based drama characters can enter and be present without being referred to, characters on radio cannot be part of the play without their presence being indicated in some way. In the face of this, radio drama and comedy has developed a method which involves announcing or indicating to the audience that a character is present. As well as descriptions of the action, such as 'look out, he's got a gun . . .,' 'noticings' such as 'isn't that Bob over there . . .' become essential to the listener's understanding of the flow, direction, and copresence within the drama. Although talk plays a major part, sounds and effects are also used but unlike a visual medium, where objects can make their presence felt by making a noise such as a seagull's cry or a train's whistle and can continue their presence when even when silent, the action, noises, and sounds within radio drama are indexical to the moment and only gain meaning through the immediate context in which they exist or are placed verbally. While this may involve, for example, the sound of sea wash giving context to the setting of the play at the beginning, sounds that occur within the production must also be fixed at the moment they are heard. As Crisell (1994) pointed out, the rustling of recording tape could be heard as a dress rustling, walking through leaves, unwrapping a parcel, or indeed the rustling of recording tape, and that while ballpark meaning can be gleaned from the context of the play, the sound gains its fixed meaning through the words surrounding the noise. Not 'seeing' may cause some limitation of the play's contextual environment, but one of the benefits of this is that without visual or indeed expensive technical features radio can place the action in any place it chooses as well as move the action between places at lightning speed.

One of the early, and still according to many the best, programs that exploited the possibilities afforded by the medium of radio was *The Goon Show*. *The Goon Show*, a series of comedy sketches written by Spike Milligan, was broadcast on the BBC from 1951 to 1960 and within each show the cast weaved a web of highly fantastic contexts and events. Through the 'blindness' of radio they were able to invent anything within a world where the laws of nature were untethered and constantly warped into an innovative canvas of infinite possibilities.

The language exploited the ephemeral nature of radio, where the fast-paced shift between places as diverse as the Wild West, the South Pole and even up a trouser leg (Crisell, 1994) combined with the 'appearance' and 'disappearance' of objects and characters, creating a surreal world where literally anything could and indeed did happen, and often between breaths. At the time this quick-fire fantastic world, where naming something brought it to life or describing something created an imagined place, would not have been possible on TV and indeed even now would cost an enormous amount of money and time.

While language and sound are important in radio drama, a further aspect of interest to language study is at the basic level of the word. Word selection within a particular play is an issue bound up with institutional politics, the reputations of the station and the playwright, dramatic realism, and listener credibility. Lewis (1992: 15) characterizes the disparate pulls and dimensions around word choice as a tug-of-war where words require careful scrutiny to avoid offense, or rather, as Goffman points out, the possibility of giving offense to others (Goffman, 1981: 244). For, apart from some words absolutely banned, the debate over which are permissible becomes a battle between the writers, producers, and management, the time of day, and on what station the drama is to be broadcast. In light of this, words have the potential to become politicized and even censured because of what might cause offense. Radio drama and comedy, or 'light entertainment,' provides a fascinating exploration into the sensitivity of words to perceived others as well as providing some of the most fertile development ground for drama and comedy, some successfully transferring to television, some not. While television provides a window on the world, radio provides a glass by which to listen to the lives of the people in the next room.

News and Current Affairs

Although radio news revolutionized international communication, coming of age during times of crisis and war, long gone are the days of the family crowding around the wireless set to hear the latest news from the voice of authority. Today television news is the choice for evening viewing, and together with the growing influence of the Internet it provides instantaneous pictures from around the world. However, while television dominates the evening and home daytime schedule, it is still radio and radio news that we invite into the innermost sanctum of our home, listen to from under the duvet in the morning, in the bathroom (even in the shower), in the car, at work, and on the way home. News remains a force of radio broadcasting, particularly the internationally renowned broadcasts of the BBC World Service, Radio Australia, Voice of America, etc. While the linguistic style of radio has changed over the years, employing a more localized, personality-based method (Scannell and Cardiff, 1991; Leitner, 1983), the voice of radio news continues to be reminiscent of the conviction expressed by Lord Reith, the first Director General of the BBC, that using regional accents would alienate or be unintelligible to the public, and of his observation that the technology was suited for the male voice. For Reith the higher-pitched female voice was considered more akin to gossip, rumor, hysteria, and irrationality rather than being heard as conveying the weightiness deemed appropriate for newsreading. And while female news presenters are now commonplace, they still tend to lower their voice when reading the news because the microphone was originally developed for the male voice and works best at lower pitch (Dyson, 1994). Radio news also tends to employ a relatively simple linguistic code similar to Basil Bernstein's restricted code, which utilizes 'colloquial terms, contains much redundancy and is oriented towards the phatic' (Crisell, 1994: 87).

The status of 'difference' attached to the news broadcast on radio is not only noticeable in the measured style and tone of delivery but also through its marked separation from other programs. The news is 'announced' before it arrives ('and now we go to the news') and then the audience and DJ are taken to another place, the newsroom, to have the news 'read' to them. Alternatively the news may be brought to the audience by the newsreader coming to the program from the 'newsroom.' Various commentators have observed the similarities between news stories and formal narratives (Bell, 1991). Higgins and Moss (1982), however, took this further and suggested news has the theatrical resonance of radio drama, where, without visuals, the spoken word and description must fill in the necessary information for the listener. Furthermore, they suggested radio news discourse sets up a dramatic frame around a series of familiar events with an expected cast of characters, which appear on cue acting in character and inviting the audience to boo, hiss, and cheer as they go through the motions. The analogy might be more akin to a soap opera rather than a play, though, for as Jaworski *et al.* (2003) suggested, news stories are often ongoing and devote a large amount of time to speculation about what might happen next within the story from the characters as well as from the 'narrator,' and so providing speculation as to the next installment.

While the soaping of news ('news-tainment') is a trend noticeable across news production, in the face of the increasing challenge from other news providers radio has managed to develop its strengths of availability, speed, and flexibility. Radio is able to cross international and political borders and broadcast to potentially millions of people without need of expensive or scarce satellite receivers, computers, or televisions, or indeed literacy. Also in terms of wider news values, radio is able to steal a march on other media. Because of radio's relatively low production costs and without the need for the technology and access required for television broadcasts, radio news can set up and broadcast quickly from a given location. In this way one of the advantages that radio news has over print and to some extent over TV is **immediacy**, the holy grail of news production and number one on the news values list, being first on the scene and first to report the latest happenings. Radio news can respond quickly to events and can get to them, set up, and broadcast before TV news. Moreover, the 'blindness' of the medium works to its advantage with early-morning interviews or news gathering, as all that is needed is a telephone or a radio car from which to conduct an interview. The journalist may give a report whilst getting breakfast ready or the politician might give an interview from his or her armchair. In this way radio news in some senses has the advantage of being 'blind' because although language must be used to convey all the information, the absence of visuals means it cannot, and so does not have to, produce images to accompany a story.

DJ Talk

While most analysis of radio language focuses largely upon stations dominated or dedicated to talk, Martin Montgomery's work (Montgomery, 1986) examined the genre of popular music radio and specifically the talk of the DJ between music tracks. Talk that occurs between music is often seen as a way to fill time although research demonstrates that, far from being a simple space filler, the talk is often constructed through a complex interpersonal dynamic using various discourse and conversational features. Connecting with some of the themes mentioned above, DJ talk is of the style of the lone voice broadcasting to an unseen overhearing mass audience attempting to create a sense of intimacy and community with the audience.

Thus, of particular note to Montgomery was the ability of the DJ to employ linguistic and discursive structures within an extended monologue, with which is created and sustained a sense of both copresent conversation and intimacy with the audience, or rather audiences. Rather, Montgomery demonstrated that DJ talk reveals an orientation to, through design for, any number of audiences, through identification of individuals or groups (both 'in' and 'out' groups) as well as the ability to shift discursive positions by using different registers.

This is done by foregrounding the interpersonal, for example by DJs commenting on the informality of address between themselves and listeners; by creating social deixis through direct address to individual members or identifiable groups of the audience, such as "hello to those listeners in Edinburgh" or "Sarah Jones, happy birthday to you"; by simulating copresence through the use of response-demanding utterances such as greetings or interrogatives; and by the use of expressives indicating a psychological state of mind when interjecting or giving comment from a written text, such as when reading the horoscopes (Montgomery, 1986). DJ talk, then, goes to the heart of much of the discussion around public and personal language where the everyday conversational structures, methods, and routines hide a premeditated construction in which the script provides the basis from which the DJ through ad-libs and asides addresses a number of different audiences, excludes others, and creates a sense of community.

Radio Phone-ins

The phone-in would seem particularly well suited to radio as the format is based on the remote listening audience being invited to phone the program and air their views on the world from wherever they are. The callers to these shows do not need any special technical equipment and do not need to be in a specific place; they can even be in the car 'on the side of the road' using a cell phone. Because of this 'access by anyone' the phone-in creates an egalitarian sense where anyone can have their say, as well as building an intimate environment around the listeners of a community centered on the host as someone the listeners can 'know' as personable, engaging, interested in their views, sometimes controversial, but above all on the side of the 'ordinary' person in the street. While for most countries the phone-in or talkback has marginal influence on wider society, acting more as a talking shop or gripe conduit, in others, for example Australia, Hong Kong, and the United States, the talkback hosts command an influential political position sometimes far beyond their TV counterparts.

The neat suitability of this type of program for radio is highlighted in instances where television attempts the same thing. In television the need for visual accompaniments often means a studio with a noticeably unseen caller, sometimes indicated by a dot on a map, speaking into the void of the studio with

the host nodding into the camera. For TV the center of the discussion becomes the studio, where the view is an animated host. On radio, however, the host goes to the caller and the coziness of phone and radio is reinforced through a linguistic sleight of hand by which the host whisks the listener around the country or city, to the place of the caller by simply saying 'and now let's go to . . . .' We are then transported to the front room of the caller, sitting with them as they give their opinion on the day's hot topics. While the supposed value to the radio station of phone-in programs lies in the opportunity to be seen as giving an avenue for listener feedback as well as demonstrating that there is in fact an audience listening, for linguistics the interest lies in the intersection between lay and professional practice found in radio phone-ins (Hutchby, 1996). As phone-in programs are usually live they cannot be scripted and therefore provide a valuable insight into radio language as the presenter responds to a particular caller on air.

The discursive organization of radio phone-ins is often around a debate format, within individual calls or entire programs, where either the host invites callers to discuss a particular topic of the day or callers select their own newsworthy topic. In some of these the host takes a neutral stance, displaying a challenging though impartial attitude to callers' opinions through an explicit shift in position according to that of the particular caller. In that sense, while spontaneous, the talk adheres to a formal structure oriented to by both host and callers. While neutrality is the goal of some phone-in programs, creating deliberate antagonistic positions is the goal of others. Here again, though, the structures by which the caller gets onto the air, the speed with which their position or opinion is initially given, and the way their interaction is controlled display a linguistic structure managed moment by moment by the host. Indeed, this management by the host ends with the ultimate control over the talk through the potential of the cut-off button. The host's job is to generate entertainment from a complete stranger they cannot see and to do so within a very short time frame. Because of this the structure used to introduce a caller onto the program becomes crucially important to the flow of the call and ultimately the success of the presenter as a phone-in host. Although the presenter and the caller have never met or spoken to each other before being on air, the caller must be brought onto the program, introduced to the listening audience and given a slot to start giving their opinion. Within this sequence the host may minimize or even exclude the possibility of greeting sequences, allowing more time for more callers. This can be seen in the example below, where the host structures the introduction in order to provide a routine amount of information about the caller, bring the caller off air to on air, and offer a first-pair part to a topic-oriented question, thus making the caller's first utterance a response to the question about the topic.

> Host: Betty Robins from Birmingham, what's your opinion on this?
> Betty: Well, I would just like to say. . .

The host's question then leaves no sequential slot for the caller to give a greeting but rather to go straight onto the reason for their call (Fitzgerald and Housley, 2002). As Hutchby (1996) pointed out, this sequential position also always places the host in a response position and so able to choose which aspect of the caller's opinion to debate and how to debate it. The host, then, is able to exercise control over the callers through the introduction but also to generate entertainment through this sequential organization by adopting a contrastive organization offering alternatives to the caller's stance. While the control of sequence enables contrasting positions to be adopted, the host can also draw out features of identity to further this contrastive debate organization. The relationship between language, identity, and knowledge is used by the host to generate a sense of who can speak on what topic (Hester and Fitzgerald, 1999). This legitimizing of a caller's stance often relies upon strategic positioning through social and topical identification in order to be heard as credible. This provides a interesting area for research into language and identity as callers cannot be seen and so they must verbally construct their status, identity, position, and hence credibility, in real time within a short time span. Phone-ins provide an avenue into the social organization of language, identity, and power through the routine acts of presenting, seeking, and negotiating which identity is salient and affords interactional space for knowledge displays and can hence be heard as a credible witness.

Radulphus Brito (also Radulphus Reginaldi Britonis and Raoul le Breton in French) was born c. 1270–1275 in Ploudiry, a tiny village in the old diocese of Léon situated c. 7 miles east of Brest, Finistère, Brittany, France (hence his naming as 'de Plebe Dyriaco' in the university records). Starting in 1296 he taught as a Master of Arts in Paris, where he also acquired his doctorate in theology in 1311–1312 and served as a provisor to the Sorbonne from 1315 to 1320, possibly the year of his death.

Radulphus was a prolific writer in many subjects: grammar, logic, philosophy, theology, and even mathematics and astronomy, and he commented on the Aristotelian corpus, on Porphyry and Boethius. His logico-grammatical sophisms and his specific understanding of the abstract and concrete first and second intentions brought him fame as a logician, and his conception of *modi significandi* in his commentary on the so-called *Priscianus minor*, the syntactical part of Priscian's textbook *Institutiones grammaticae* (books 17 and 18), made him a leading speculative grammarian (cf. Enders, 1980). Thus he influenced the work of another important Modist, viz. Thomas of Erfurt.

Most of Radulphus' work is still unedited (cf. Pinborg, 1980: 15–19). Deuffic (2002) gathers remarks on the extant manuscripts and lists the literature on Radulphus from 1850 to 2001.

See also: Thomas of Erfurt (fl. 1300).

Rajarajavarma, A. R. (1863–1918)

J-L Chevillard, CNRS, Université Paris 7, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

A. R. Rajaraja Varma, also known as *Kēraḷa Pāṇini*, is famous for being the author of a work called *Kēraḷa Pāṇinīyam*. According to K. N. Ezhuthachan (1974: 254), this "most important grammatical work in Malayalam has not been surpassed by other works since its publication in 1896, and especially after its revised edition in 1917." The author was a grammarian of Sanskrit and Malayalam, and composed books in both languages. From 1911 onward, he was the Head of the Language departments of the Mahajara's College in Trivandrum. In the preface to the second edition (quoted here from the 1999 English translation by C. J. Roy), written one year before his death, he starts by stating that there are two ways to compile a grammar, first, an 'inferential' (*abhyūhika*) way, where one has to "observe closely [...] the basic units of the language at a particular period and arrive at certain conclusions" and second, a 'historical' (*āgamika*) way, where one has to "trace the history of the language from its origin, find out the changes it had [...] and formulate rules to suit them." Opposing these two methods, he states that "the former is easier" but "the latter is more useful," and that "if grammar is to be treated as a science, it should be historical." He even goes to the extent of comparing inferential grammar with 'dictatorship' and historical grammar with 'democracy.' Using this general frame, he then explains that the 1896 edition of his grammar, written "out of childish inquisitiveness," was at the same time inferential and historical, that the only thing really common between it and the new book, mostly based on lectures he gave in the classroom, was the title. He then proceeds to give a list of works that were "of maximum use." This list includes, among others: Caldwell's Comparative Grammar of Dravidian languages (*see* **Caldwell, Robert (1814–1891)**), the medieval Tamil grammar called Naṉṉūl (*see* **Tamil Linguistic Tradition**), the *Malayāḷā [Bhāṣā] Vyākaraṇam* by H. Gundert (1814–1893), from whom he borrowed examples and the 14th century *maṇipravāḷa* grammar called *Līlātilakam*.

Ralph of Beauvais (fl. 1175)

L Kaczmarek, Borgholzhausen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Little is known about the life of the Englishman Ralph of Beauvais (known to his contemporaries as Radulfus Bellovacensis or Belvacensis), who in the 1130s came to France to study under Abelard (d. 1142) and later took over teaching at the Cathedral School of Beauvais for the rest of his career. Ralph died in France after 1180. Hunt (1980) and Kneepkens (1991) have gathered what can be reconstructed about him from historical sources.

Ralph of Beauvais' work on grammar survives in two texts (edited by Kneepkens in 1982 and 1991, respectively) that cannot be grouped as commentaries or textbooks: the *Glose super Donatum*, which is a commentary on Aelius Donatus' 4th-century elementary grammar textbook known as the *Ars minor*, and the *Liber Tytan*, which expands on lines taken from Lucan, Ovid, and Virgil, among others. There are strong doctrinal relations of these works (see the Indices Locorum) to the anonymous Priscian gloss commentary known as *Promisimus* (now edited in Fredborg, 1999) and to the rather elementary *Verba preceptiva*.

Like other conservative-oriented grammarians from the 12th century such as William of Conches and Peter Helias, Ralph of Beauvais was interested in explaining constructions from the texts of classical authors. What he had to say about the concept of government deserves a second look. He makes use of the terminology of *regere* and *exigere*, the concepts of which he differentiates on syntactical and semantical grounds.

Although he never tried to sell originality in linguistic theory, Ralph was held in high esteem as a thorough grammarian and influential school teacher. Since the findings of Hunt (who even assumes a 'school' of Ralph of Beauvais), some of his pupils and followers have been identified, viz. Petrus Hispanus (non-papa), Robert Blund, and Robert of Paris. The 13th-century speculative grammarian Michael of Marbais criticizes aspects of the theories held by Ralph.

Ramat, Paolo (b. 1936)

D Stein, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

© 2006 Elsevier Ltd. All rights reserved.

After graduating in linguistics and comparative philology at the University of Florence and holding several teaching positions in Germany, Paolo Ramat was appointed full professor of Germanic Philology at Cagliari and Pavia in 1971, and as full Professor of Linguistics at Pavia in 1974. He has held numerous posts as guest professor at universities in Germany, France, Czechoslovakia, and the United States, and has also served as President of the International Society of Historical Linguistics. He has held several prominent positions in national and international scientific societies, such as at the Congrès International de Linguistique and as representative of the Consiglio Nazionale delle Ricerche at the European Science Foundation. Ramat has also played a prominent role in several European-based research initiatives, such as the EUROTYP project.

Ramat is primarily a historical and comparative linguist, with his work firmly embedded in a wide vista encompassing cultural theory and archeology. He has published extensively on a broad range of European languages, ranging from Frisian to Greek, and has shared this interest with his wife, Anna Giacalone Ramat, with whom he coauthored a number of seminal studies in this area, centering on Indo-European languages. Ramat has analyzed a range of structures from the typological point of view, such as sentence adverbs, relative sentences, negation, and auxiliaries. Ramat's historical-linguistic orientation is linked to a theoretical interest in typology and universals. He has argued in favor of local, rather than holistic, typology. A related pursuit is the nature of linguistic categories, where he has argued for a coalescence of both formal (syntactic and morphosyntactic) and semantic criteria. From such a perspective, the traditional 'parts of speech' appear to be well-founded candidates for universal categories. He has also taken issue with current grammaticalization theory, with its axiom of the unidirectionality of grammaticalization. He has argued that there are several cases that suggest the existence of the opposite route, with grammatical items developing into full lexical items, suggesting a complementary line of development and a spiraling development as a better representation of linguistic development. Paolo Ramat's work has had a major impact (not only) in European historical linguistics.

From the very beginning of his life, Gustaf John Ramstedt, as the child of a Swedish family in Finland (which belonged at that time to the Russian Empire) was acquainted with a multilingual and multiethnic situation that stimulated his early interest for different languages and cultures. He studied Latin, Greek, Hebrew, and Sanskrit at the University of Helsinki. In 1895, he finished his studies and worked for two years at the Finnish high school in Turku as a teacher of Swedish.

In 1898, Otto Dooner, a university professor of Ramstedt's and president of the Finno–Ugrian Society, invited him to Helsinki to start a wide-ranging program of investigation of Uralic and Altaic languages. In the course of this project, Ramstedt undertook, between 1898 and 1912, several journeys through the Russian Empire to Mongolia and Chinese Turkestan. He started his field studies with a Uralic language, Mari (Cheremis), near the Volga River (cf. Ramstedt, 1902), but his subsequent activity was dedicated to Altaic languages. In his dissertation, Ramstedt used Mongolian (Khalkha Mongolian) data collected during his first visit to Mongolia in 1898–1901 (Ramstedt, 1903). Later he studied another Mongolian language, Kalmyk (Kalmyk-Oirat; Ramstedt, 1909–1919) and compiled a Kalmyk dictionary, which was for a long time the main source for this language (Ramstedt, 1935). Ramsted investigated the Turkic languages in Northern Caucasus, and in 1903 he traveled to Central Asia up to the Afghan border to study Mogholi, a Mongolian language of a small isolated ethnic group in Afghanistan. His report was the first scientific description of this language (Ramstedt, 1906). During these journeys Ramstedt not only studied the spoken languages, but also collected different written sources, contributing to the study of the Old Turkic epigraphy (cf. Ramstedt, 1918). In 1906, Ramstedt became associated professor for Altaic languages, and in 1917, professor extraordinarius of Altaic philology at the University of Helsinki.

In 1919, Ramstedt's scientific career was interrupted by the intrusion of political events into his life. The young Finnish Republic (Finland proclaimed its independence in 1917) had to build up its foreign policy but possessed no professional diplomats. As an esteemed Orientalist, Ramsted was nominated the first Finnish diplomat in eastern Asia, the Finnish chargé d'affaires in Japan, where he stayed till 1929. Ramstedt used his time in Japan to continue his linguistic work: he studied Japanese and above all Korean, which became from this time on one of his main concerns. Ramstedt's *A Korean grammar* (1939) was a significant step in the study of this language.

After his return to Helsinki, Ramstedt resumed his academic activity at the university and in the Finno–Ugrian Society (he was president of the society from 1944 to 1950). He taught courses on Asian languages, including Mongolian, Kalmyk, Korean, Japanese, and Manchu. However, his main interest was dedicated to the comparative study of Altaic languages. He started his activity in this field quite early (cf. Ramstedt, 1907), but initially Ramstedt was quite cautious as to the point of genetic relation of Altaic languages, stating rather the fact of affinities between them. Later he was more and more convinced of the genetic (not only typologic or contact) unity of Altaic languages (cf. Ramstedt, 1912). The analysis of Korean led him to a conclusion that this language is a part of the Altaic family. Ramstedt did not exclude the possibility that Japanese is also an Altaic language, but stated that this question "can not yet be clarified" (Ramstedt, 1952–1966 I: 14). For decades, Ramstedt analyzed the phonetic and grammatical correspondences within the Altaic family; sometimes he had to clear the subgrouping of languages in one branch of the language family, cf. his investigation on the position of Chuvash among Turkic languages (Ramstedt, 1922). Ramstedt was the first linguist to transform a vague idea about the original unity of the huge linguistic area from the Volga river to the Pacific Ocean, including Turkic, Mongolian, Manchu, and Korean languages, into a strong scientific concept. His main work in Altaic linguistics was a comparative grammar of Altaic languages, published posthumously (1952–1966). Ramstedt's scientific heritage was voluminous, and publications, carrying his name, appeared for a long time after his death (cf. Ramstedt, 1973–1974; 1982). N. Poppe named Ramstedt "the real founder of modern Mongolian linguistics and Altaic comparative studies" (Poppe, 1965: 83), and this statement was endorsed by the common opinion of linguists.

Pierre de la Ramée, a French humanist, mathematician, and philosopher, better known as Petrus Ramus, is credited with having introduced formalism in linguistics and has sometimes been hailed as a precursor of modern structuralism.

He was born in Cuts (Vermandois) in 1515. He evinced his hostility to the Aristotelian and scholastic tradition in his M.A. thesis (1536), which brought about the disapproval of the Sorbonne. He nevertheless became a professor in the Royal College (*Collège de France*) in 1551, after being the Principal of the *Collège de Presles* (1545). Embracing the Reformation (1561), he had to give up his professorship, which he resumed after the Amboise peace treaty, from 1663 to 1567. After touring Switzerland and Germany (1568–1570), he went back to Paris, where he was assassinated in the massacre of St. Bartholemew (August 26, 1572).

Ramus's linguistic thought, which constantly evolved, has been described as 'prestructuralist,' because it is essentially founded on the study of variation and distribution of word forms, and not on semantic criteria. After dividing the contrasting areas of grammar, dialectic, and rhetoric, Ramus, claiming Plato's authority, exclusively used dichotomy in analyzing linguistic material, which led him to reduce the traditional distinctions between several terms in binary oppositions. While he set down his theory in his *Scholae grammaticae*, Ramus also wrote grammars of Latin, Greek, and French (the latter with reformed spelling). Breaking away from Latin tradition, he refused the then-used expression 'parts of speech' (*partes orationis*) and classified words (*uoces*) into two categories (declinable or indeclinable), which, once redistributed, produced four categories, associated in pairs: nouns-verbs, adverb-conjunctions. Establishing such wide word classes and so few syntactic rules enabled him to avoid recategorizing words from one class into another, but compelled him to acknowledge that their associations were constantly disrupted. Ramus gathered those disruptions under the name of 'anomalies,' giving up the usual system of figures of construction (Colombat, 1993: 196–208). In 1572 Ramus introduced the Latin system of cases into his French grammar, previously built on a study of how the forms were arranged, which shows the failure of a purely formal grammar (Chevalier, 1968).

Influenced by Rudolph Agricola and collaborating with Omer Talon, Ramus carried out a redistribution of the fields between dialectic and rhetoric; regarding

He was born in Cuts (Vermandois) in 1515. He evinced his hostility to the Aristotelian and scholastic tradition in his M.A. thesis (1536), which brought about the disapproval of the Sorbonne. He nevertheless became a professor in the Royal College (*Collège de France*) in 1551, after being the Principal of the *Collège de Presles* (1545). Embracing the Reformation (1561), he had to give up his professorship, which he resumed after the Amboise peace treaty, from 1663 to 1567. After touring Switzerland and Germany (1568–1570), he went back to Paris, where he was assassinated in the massacre of St. Bartholemew (August 26, 1572).

Ramus's linguistic thought, which constantly evolved, has been described as 'prestructuralist,' because it is essentially founded on the study of variation and distribution of word forms, and not on semantic criteria. After dividing the contrasting areas of grammar, dialectic, and rhetoric, Ramus, claiming Plato's authority, exclusively used dichotomy in analyzing linguistic material, which led him to reduce the traditional distinctions between several terms in binary oppositions. While he set down his theory in his *Scholae grammaticae*, Ramus also wrote grammars of Latin, Greek, and French (the latter with reformed spelling). Breaking away from Latin tradition, he refused the then-used expression 'parts of speech' (*partes orationis*) and classified words (*uoces*) into two categories (declinable or indeclinable), which, once redistributed, produced four categories, associated in pairs: nouns-verbs, adverb-conjunctions. Establishing such wide word classes and so few syntactic rules enabled him to avoid recategorizing words from one class into another, but compelled him to acknowledge that their associations were constantly disrupted. Ramus gathered those disruptions under the name of 'anomalies,' giving up the usual system of figures of construction (Colombat, 1993: 196–208). In 1572 Ramus introduced the Latin system of cases into his French grammar, previously built on a study of how the forms were arranged, which shows the failure of a purely formal grammar (Chevalier, 1968).

Influenced by Rudolph Agricola and collaborating with Omer Talon, Ramus carried out a redistribution of the fields between dialectic and rhetoric; regarding

the latter, he intended both to evince a creative opposition to the received texts of antiquity and to promote the French language (Meerhoff, 1986).

The extreme formalism of Ramus may set him apart in the history of linguistics. Ramism has nevertheless left deep marks, and has particularly influenced Sanctius, Port-Royal, and North European grammarians.

Rask, Rasmus Kristian (1787–1832)

A Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Rasmus Kristian Rask was one of the triumvirate of 'mighty monosyllables' (alongside Franz Bopp and Jacob Grimm), credited with instigating the historical-comparative approach, which would dominate serious language study throughout the 19th century. While Rask's name is invariably mentioned alongside Grimm and Bopp, his work as a whole is not as well known to historians of linguistics as that of the other two, and the sheer breadth of what he achieved in his short lifetime is not fully appreciated, at least in part because he insisted on writing in Danish. The Danish language was, by his own admission, Rask's greatest love, and he worked tirelessly to give Danish greater prestige, for example by devising a new orthography for the language and creating a set of Danish rather than Latin-based linguistic technical terms. However, he published only one Danish grammar as such, the 1830 *Grammar of the Danish language for the use of Englishmen*.

Rask is best known in linguistics for his pioneering studies of Old Norse and Old English, two key languages for the study of Germanic philology, and the 1811 *Vejledning til det Islandske eller gamle Nordiske Sprog* was the first historical grammar of an Indo-European language. Rask was more of a comparer than a historian of languages, however, and he wrote an extraordinary number of studies of different languages, many of them pioneering, in order to compare their forms. A glance through the bibliography of his published work alone (Rask, 1932/1935, III: 337–385)—and the list of unpublished writings runs to a further 79 pages (Bjerrum, 1968: 515–594)—reveals, for example, studies of English, Spanish, Frisian, Sámi (Saami Inari), Greenlandic (Inuktitut, Greenlandic), Pali, and numerous other, chiefly Indo-European, languages besides. In several cases, such as the Sámi grammar of 1832 and an 1828 grammar of the Kwa language Gã (spoken in Ghana [formerly the Danish-colonized Gold Coast]), he was working with material presented in earlier grammars.

Rask had a brilliant mind and a prodigious talent for analyzing and systematizing languages, but he did

the latter, he intended both to evince a creative opposition to the received texts of antiquity and to promote the French language (Meerhoff, 1986).

The extreme formalism of Ramus may set him apart in the history of linguistics. Ramism has nevertheless left deep marks, and has particularly influenced Sanctius, Port-Royal, and North European grammarians.

Rassadin, Valentin Ivanovich (b. 1939)

O Molchanova, Uniwersytet Szczecinski, Szczecin, Poland

© 2006 Elsevier Ltd. All rights reserved.

Valentin Ivanovič (Ivanovich) Rassadin was born in Pskov (the Russian Federation) in 1939. He is a Russian scholar, specializing in phonetics, dialectology, lexicology, etymology, and comparative studies of the Mongolian and Turkic languages of Mongolia and Siberia.

Rassadin was educated at the University of Leningrad (present St Petersburg), where he studied Mongolian languages and mastered his knowledge of Modern and Old Turkic languages. After his graduation, Rassadin worked as an interpreter in Mongolia for a year and later took up postgraduate courses in Turkic languages at the University in Novosibirsk. He received his M.A. for his thesis titled 'Lexicon of the modern Tofa language' in 1967 and his Ph.D. for his dissertation 'The Tofa language and its place in the system of other Turkic languages' in 1983. During a span of little less than 20 years between the two degrees, Rassadin's scholarly achievements were considerable and received wide recognition.

In his investigations, he fully recognized the importance of fieldwork in linguistic analysis. He gathered data firsthand from native language bearers during his numerous field trips in Russia, Mongolia, and China. In his books and papers, Rassadin made a point of describing and theorizing only on the basis of firsthand material. In line with this, he researched the historical phonetics of the Byrjat (Buriat) language, the systematic description and comparative studies of unexplored Burjat dialects, and the impact of Mongolian languages on Siberian Turkic languages.

Rassadin emphasized the importance of a descriptive approach to language, both in its own right and as a necessary preliminary to historical and comparative linguistics, based on contemporary, medieval, and old Mongolian and Turkic languages.

Rassadin's great contribution to Turkology is his research on the modern Tofa (Karagas) language, which has continued for more than 30 years. Tofa is a Siberian Turkic language that did not have any records and existed only in its oral form within a small community of reindeer breeders, who numbered 720 in 1989. Not only did Rassadin present a scholarly description of the language but he also created its written form and rules of orthography. Owing to Rassadin's research, the Tofa language was introduced into primary education in the Sayan region in 1990. Tofa teachers and children use ABCs and grammar books written by Rassadin.

During his first field trips to Burjatia (the Oka region) in the 1970s, he gathered linguistic material of another Siberian Turkic language, Sojot, considered to be extinct. As with Tofa, Rassadin created a system of writing for the Sojots, wrote ABCs and grammar books for their schools, and compiled *A Sojot–Burjat–Russian dictionary.* Thus, he both saved the language and tried to revive it.

Rassadin is also known as a translator of O. Böhtlingk's book *Über die Sprache der Jakuten* into Russian (1989).

Under his guidance, 30 scholars obtained their masters' and four their doctorate degrees. Rassadin has received many honors, including election to the Academy of Sciences (Russia, Finland), the title of Honored Scientist of Burjatia and the Russian Federation, the Russian Order of Friendship, and the Burjat Medal of Aldar solo. Rassadin has held various posts

not lead a terribly healthy or happy life. He never achieved the high academic office he felt he deserved, and he tended to publish what he wanted to publish rather than what his superiors wanted him to publish. He died, rather embittered and unstable, still only in his mid-40s. This fact, coupled with his relatively humble origins on the Danish island of Fyn, has made him a rather romantic figure in Danish intellectual history.

Rassadin emphasized the importance of a descriptive approach to language, both in its own right and as a necessary preliminary to historical and comparative linguistics, based on contemporary, medieval, and old Mongolian and Turkic languages.

Rassadin's great contribution to Turkology is his research on the modern Tofa (Karagas) language, which has continued for more than 30 years. Tofa is a Siberian Turkic language that did not have any records and existed only in its oral form within a small community of reindeer breeders, who numbered 720 in 1989. Not only did Rassadin present a scholarly description of the language but he also created its written form and rules of orthography. Owing to Rassadin's research, the Tofa language was introduced into primary education in the Sayan region in 1990. Tofa teachers and children use ABCs and grammar books written by Rassadin.

During his first field trips to Burjatia (the Oka region) in the 1970s, he gathered linguistic material of another Siberian Turkic language, Sojot, considered to be extinct. As with Tofa, Rassadin created a system of writing for the Sojots, wrote ABCs and grammar books for their schools, and compiled *A Sojot–Burjat–Russian dictionary.* Thus, he both saved the language and tried to revive it.

Rassadin is also known as a translator of O. Böhtlingk's book *Über die Sprache der Jakuten* into Russian (1989).

Under his guidance, 30 scholars obtained their masters' and four their doctorate degrees. Rassadin has received many honors, including election to the Academy of Sciences (Russia, Finland), the title of Honored Scientist of Burjatia and the Russian Federation, the Russian Order of Friendship, and the Burjat Medal of Aldar solo. Rassadin has held various posts

at the Institute of Mongol, Buddhism and Tibet Studies. In 1992, he founded a new Department of Central Asian Philology at the University in Ulan-Ude.

At present, Rassadin is Chair and Professor of the Department of Central Asian Philology and Senior Researcher at the Institute of Mongol, Buddhism and Tibet Studies in Ulan-Ude. He has published more than 130 books and papers.

Rastafari Language

V Pollard, Kingston, Jamaica

© 2006 Elsevier Ltd. All rights reserved.

The language of Rastafari is one of a small number of codes created to serve the specific needs of a particular group. Labeled variously 'I-ance,' 'I-yaric,' 'Rasta Talk,' and 'Dread Talk,' it is the expression of the philosophy of a socioreligious movement that emerged in Jamaica in the 1930s in response to a social reality that placed the poor, black man at the bottom of the society. That man saw himself as dispossessed, pressed down economically and socially by the establishment. The language that evolved reconstructed English words so as to represent him accurately. So, for example, pressed 'down' by society he refused to label his condition 'oppressed,' a word whose direction, in the logic of English, is 'up.' He created the word 'downpressed.' The process for this transformation was one of many processes English words were made to undergo.

In the reconstruction of words, the sound /ai/ 'I' became a particularly significant sound. English, the major lexifier of all language in Jamaica, would see little relationship between *I* (ego) and *eye* the organ of sight. In the code of the Rastafari, however, where sound is paramount, the relationship between the two is close and obvious. Any word from English easily becomes a new word in Rastafari 'wordology' by changing the initial syllable to *I*. So, for example, *vital*, which describes food that is good for the body, becomes *Ital*.

Nettleford (1976: vii) described Rastafari as "one of the most significant phenomena to emerge out of the modern history and sociology of Plantation America." Later, quoting Theodor Adorno, Nettleford commented that "Social protest manifests itself in language change. For defiance of society includes defiance of its language" (Nettleford, 1978: 18). Dread Talk reflects the impact of the Rastafari movement on the Jamaican speech situation and it shares the movement's significance.

Today the language of Rastafari has spread not only beyond the group to the wider Jamaican society but also beyond the boundaries of Jamaica to the international community thanks to the music of Reggae and the lyrics of that music on the tongues of outstanding musicians like Bob Marley and Peter Tosh. There are communities of Rastafari not only in other Caribbean islands and in England and the United States, where large numbers of Jamaicans live, but also, for example, in Brazil, Japan, Italy, New Zealand, and Ghana.

Within Jamaica, the language has moved from being the language of a dispossessed minority to being a code in more general use. What could hardly have been predicted is that the words would become absorbed into the formal/official language of

Rational Analysis and Language Processing

N Chater, University of Warwick, Coventry, UK

© 2006 Elsevier Ltd. All rights reserved.

The Project of Rational Explanation

The biological and social sciences frequently aim to provide rational explanations for the phenomena they study. In biology, rational explanations typically are grounded in evolutionary theory – rational outcomes are presumed to be selected by natural selection (McNamara, Houston, and Collins, 2001). In the social sciences, rational explanations typically are framed by reference to motives and goals of social agents, as formalized in rational choice theory (Elster, 1986). To the extent that language is viewed as a biological or social phenomenon, it seems natural to apply rational explanation to attempt to understand why language processing, and indeed language itself, has the structure that it does. Attempts to provide explanations of this kind have been widespread, although piecemeal, from the earliest attempts to study language systematically. Here, we organize the discussion using a specific framework for constructing rational explanations, the methodology of rational analysis developed by the cognitive psychologist John Anderson. We outline the approach in the next section, and illustrate it in three domains of language processing in the next. Finally, we consider the future prospects for rational approaches to cognition.

Rational Analysis

Cognitive science, including the cognitive science of language processing, has focused on descriptions of the representations and processes involved in cognitive behavior. Anderson (1990) argued that a complementary project, that of providing explanations for these processes and representations, had been neglected. His methodological starting point, paralleling those in biology and the social sciences, was that cognitive phenomena can be explained as optimally adapted to achieving some goal, given specific environment and computational constraints. Specifically, his methodology of rational analysis has six steps:

1. Specify the relevant goals of the cognitive system
2. Create a simple formal model of the environment in which the agent operates
3. Make minimal assumptions about the computational constraints on the agent
4. Derive optimal performance in achieving the goal, given the environmental and computational constraints
5. Test the predictions from step 4 against empirical results
6. Iterate, to bring predictions and empirical results into line, where required.

This methodology has since been successfully applied across a wide range of cognitive domains, including memory, reasoning, categorization, search, and language processing (see Anderson, 1990; Oaksford and Chater, 1999). Note that, in this approach, rational explanation is not *a priori*. Rather, it requires making three types of empirical hypothesis (steps 1–3) about the cognitive system; and these hypotheses may be subject to independent empirical test. At step 4, these hypotheses are combined with mathematical analysis (typically, but not necessarily, from probability theory

the island, although literary publications, particularly poetry, had long been using them as a means of invoking the presence of the Rasta man. Here is an excerpt from a recent editorial in a local daily:

The Project of Rational Explanation

The biological and social sciences frequently aim to provide rational explanations for the phenomena they study. In biology, rational explanations typically are grounded in evolutionary theory – rational outcomes are presumed to be selected by natural selection (McNamara, Houston, and Collins, 2001). In the social sciences, rational explanations typically are framed by reference to motives and goals of social agents, as formalized in rational choice theory (Elster, 1986). To the extent that language is viewed as a biological or social phenomenon, it seems natural to apply rational explanation to attempt to understand why language processing, and indeed language itself, has the structure that it does. Attempts to provide explanations of this kind have been widespread, although piecemeal, from the earliest attempts to study language systematically. Here, we organize the discussion using a specific framework for constructing rational explanations, the methodology of rational analysis developed by the cognitive psychologist John Anderson. We outline the approach in the next section, and illustrate it in three domains of language processing in the next. Finally, we consider the future prospects for rational approaches to cognition.

Rational Analysis

Cognitive science, including the cognitive science of language processing, has focused on descriptions of the representations and processes involved in cognitive behavior. Anderson (1990) argued that a complementary project, that of providing explanations for these processes and representations, had been neglected. His methodological starting point, paralleling those in biology and the social sciences, was that cognitive phenomena can be explained as optimally adapted to achieving some goal, given specific environment and computational constraints. Specifically, his methodology of rational analysis has six steps:

1. Specify the relevant goals of the cognitive system
2. Create a simple formal model of the environment in which the agent operates
3. Make minimal assumptions about the computational constraints on the agent
4. Derive optimal performance in achieving the goal, given the environmental and computational constraints
5. Test the predictions from step 4 against empirical results
6. Iterate, to bring predictions and empirical results into line, where required.

This methodology has since been successfully applied across a wide range of cognitive domains, including memory, reasoning, categorization, search, and language processing (see Anderson, 1990; Oaksford and Chater, 1999). Note that, in this approach, rational explanation is not *a priori*. Rather, it requires making three types of empirical hypothesis (steps 1–3) about the cognitive system; and these hypotheses may be subject to independent empirical test. At step 4, these hypotheses are combined with mathematical analysis (typically, but not necessarily, from probability theory

and statistics) to provide rational predictions. Note that step 4 may sometimes be too strong – focusing on optimal performance may not be appropriate, particularly when similar levels of performance may be obtained in different ways. In these circumstances, rational analysis is likely to be less useful. Note, also, that the steps of the analysis will not typically be represented by the cognitive system – so that, for example, goals typically will not be available to introspection. The rational explanation of cognitive processes, including language processing, may therefore be no more consciously available to language users than the principles of aerodynamics are available to a bird that exploits them (Marr, 1982).

Illustrations

We consider three case studies of rational analysis, relevant to language processing, ranging from the lexicon, to parsing, and language acquisition.

The Lexicon and Lexical Access

We begin in a simple setting. Suppose that one goal of the cognitive system is to encode information using the minimal amount of phonological material. Suppose that we assume that, to a first approximation, an utterance consists of a sequence of conceptually (although not acoustically) discrete words. Our assumption about the environment is trivial: that phonological information is transmitted sequentially; and we ignore cognitive limitations. One consequence of these observations is that frequent words should be assigned less phonological material than infrequent words. Indeed, according to information theory (*see* **Information Theory**), word length should be inversely proportional to log frequency. Zipf (1949) observed that this qualitative relationship is approximately true – although there are many exceptions (e.g., short, low frequency words such as *sot*). We may, moreover, ask more generally about why it is that words have different frequencies at all – Mandelbrot (1953) provides an information-theoretic argument, which predicts the known frequency relationship, Zipf's Law – that the log rank position of a lexical item (where items are ranked by frequency) is negatively linearly related to its absolute log word frequency (*see* **Zipf, George Kingsley (1902–1950)**).

Let us consider the goal that the cognitive system seeks not merely to pack in as much information as possible into the speech signal but also to allow this information to be decoded incrementally, as fast as possible. Making this precise could take a number of forms – but it rules out, for example, highly efficient codes frequently used in engineering, in which the sequential structure of a signal is scrambled and unscrambled to compress it most efficiently. Thus, we may speculate that the cognitive system does not use these methods because unscrambling can only begin once an entire chunk of linguistic material has been received. We have established that discrete informational units may be appropriate – this is one motivation for using reasonably discrete words in the acoustic signal (this issue is orthogonal to the question of compositionality of the underlying – unscrambled – linguistic representation; although a rational analysis based on the need for the ability to create a large number of messages from a relatively small number of components can readily be envisaged).

Consider now, the process of lexical access. Suppose that recognizing words involve a competitive search in a mental lexicon (this proposal, at step 3, could be made precise using many different computational models, ranging from serial search to many different parallel models). The degree of confidence that a lexical item has been identified correctly should depend on the amount of linguistic evidence for that item, and the prior belief that the item will occur (the rational justification for this comes from Bayes's theorem, from probability theory). Thus, other things being equal, we should expect frequent lexical items to be identified especially quickly, and with more degraded speech input. We should also, more generally, expect word identification to be more successful for predictable versus unpredictable linguistic material, under degraded conditions, because the prior belief in the correct word will be high in these circumstances. Similar arguments can be made to explain semantic priming (e.g., Lund, Burgess, and Atchley, 1995) – that semantically related words facilitate each other's identification. Finally, notice that our rational constraint that the cognitive system aims to identify words as rapidly as possible will automatically imply that words are recognized at their uniqueness point (i.e., at the point in speech at which no other word fits the context), which is also observed (Marslen-Wilson and Welsh, 1978).

Rational analysis in this, and any other area, can be challenged and extended. For example, rich constraints from articulatory phonology may affect which strings are appropriate for words; the need for redundancy may be required to explain the prevalence of rich and partially language-specific phonological constraints; and the frequency distribution of sublexical units may be important (e.g., Brown, 1998).

Syntactic Ambiguity Resolution

The syntactic structure of languages is massively locally ambiguous. For example, a fragment such as *John*

realized may be viewed as consistent with a complement clause, such as *that his goals were unattainable* or an object *his goals*. Let us assume that the goal of the language processor is incremental interpretation (step 1); the 'environment' is simply highly locally ambiguous natural language (step 2); and suppose that the cognitive system is constrained to consider parses serially (step 3) – this assumption is particularly controversial, and might be modified by psycholinguists who believe that the parser can consider several parses in parallel.

How should a serial parser decide which locally ambiguous reading to choose? If the parser cannot recover from mistakes, then a natural rational analysis will conclude that the most probable reading should be chosen at each point. The virtue of this approach is that it leads to the greatest probability of a globally correct parse. A consequent issue is how the most probable reading is estimated – a natural approach is to use corpus frequencies of the relevant structures, given relevant lexical items (e.g., comparing the frequencies of the different readings for the specific verb *realized*). According to this type of analysis, the parser will presume that *realized* takes a complement clause. This approach is consonant with likelihood-based models of parsing (Jurafsky, 1996), although some approaches of this kind assume limited parallelism.

If, however, we take into account the fact that the parser can abandon incorrect hypotheses, and adopt previously discarded alternatives, then the picture is different. Specifically, suppose that the probability of correcting a mistake depends on how early that mistake is detected. Then there will be a tendency not merely to favor parses that are probably right but also parses that, if wrong, can rapidly be rejected. Consider two possible continuations of our example sentence, exemplifying each type of parse:

John realized (that) his shoes were muddy

John realized his goal of running a 4 minute mile

If *realized* is construed as a transitive verb, then this hypothesis can typically rapidly be rejected (e.g., as soon as *that* is encountered; or at the next noun phrase, here *his shoes*, because so few noun phrases are appropriate objects for *realized*). Hence, recovery from this error may be possible. Conversely, if *realized* is interpreted as taking a complement clause, it typically will only be rejected much later, and typically at the end of the sentence. This is because the complement-clause interpretation, even when incorrect, cannot quickly be ruled out – for example, *John realized his goal of running a 4 minute mile* . . . could continue . . . *was unattainable*. Thus, a serial (or limited parallel) parser with recovery may rationally choose parses that make highly specific (and hence quickly falsified) initial parses, even when these may not be the most probable. A detailed rational analysis embodying this viewpoint is given in Chater, Crocker, and Pickering (1998); see also Pickering, Traxler, and Crocker (2000) for relevant psycholinguistic evidence.

Language Learnability

For our final example, we briefly consider the problem of language acquisition, in which methods of rational analysis, of varying degrees of formality, have been widely used (*see* **Formal Models and Language Acquisition**). A classic perspective on the problem is that the goal of language acquisition is to correctly distinguish all and only the acceptable strings of natural language (step 1), that the environment consists of a finite set of positive linguistic data only (i.e., children are not given labeled negative data – i.e., ungrammatical sentences, labeled as such); and this data is generated by some universal computational procedure (e.g., transformational syntax) (step 2); and the cognitive system learns using some computable procedure (step 3). In this framework, Gold's (1967) theorems indicate that there is no optimal procedure (step 4) that can reliably attain this goal in the limit. This result can be viewed as evidence that innate constraints must guide language acquisition (e.g., Pinker, 1979). By contrast, a different rational analysis might take a different idealization – e.g., revising step 1 so that the goal is a high probability of correct grammaticality judgements, and revising step 2, so that the language is generated by a phase structure grammar (e.g., Horning, 1969). Given these modifications, step 4 can be carried out – there is an optimal procedure for learning, without recourse to innate language-specific information. Moreover, some theorists might argue that the appropriate goal is prediction or comprehension, or production, rather than learning grammaticality judgements at all (Rohde and Plaut, 1999). The question of the appropriate rational analysis for language acquisition is a rich one (e.g.., MacWhinney, 2004); and will depend on the empirical defensibility of the assumptions in steps 1–3, as well as the ability to accommodate rational analysis to predicting detailed data on language acquisition (steps 5–6).

Prospects

Rational explanation of language processing is attractive yet relatively undeveloped. It is attractive because it promises to explain why specific cognitive mechanisms are as they are; and it aims to explain empirical phenomena in a way that abstracts away from specific

algorithmic implementation. Nonetheless, rational analysis must be pursued in parallel with studies of computational mechanism, the linguistic environment, and empirical data on language processing – these all feed into the construction of a rational explanation of any aspect of language processing. It seems inevitable that questions of *how* language, and language processing, work will inevitably be entwined with questions of *why* they are as they are. The methodology of rational analysis provides a useful framework for answering these latter questions.

Ratke, Wolfgang (1571–1635)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Wolfgang Ratke was born in Wilster, Germany, on October 18, 1571. He studied at Rostock University and, from 1603 to 1610, taught in Amsterdam. In 1612 he presented a famous *Memorandum* (Memorial) at the election of the Holy Roman Emperor in Frankfurt, in which he offered to show how "Hebrew, Greek, Latin and other languages may be easily learned and disseminated, even in a short space of time, both to young and old." From 1614 to 1622, Ratke worked – less than successfully, it must be said – on innovative school projects in Augsburg, Köthen, and Magdeburg; from 1622 onward, he concentrated on his encyclopedic program. He died in Erfurt on April 27, 1635.

Ratke's program was dictated by his encyclopedic concept of education, which he saw as a solution to the social and political problems associated with the Thirty Years' War. It was probably conceived as a Lutheran alternative to the curricular program of the Roman Catholics and the Reformed Church.

Ratke realized early the importance of the native language as both a medium of instruction and a foundation for teaching other languages. He identified the same problem as Henry VIII and Mulcaster – the multiplicity and diversity of grammars and ways of teaching. But whereas Henry prohibited the use of all grammars in schools except one (Lily and Colet,

algorithmic implementation. Nonetheless, rational analysis must be pursued in parallel with studies of computational mechanism, the linguistic environment, and empirical data on language processing – these all feed into the construction of a rational explanation of any aspect of language processing. It seems inevitable that questions of *how* language, and language processing, work will inevitably be entwined with questions of *why* they are as they are. The methodology of rational analysis provides a useful framework for answering these latter questions.

Wolfgang Ratke was born in Wilster, Germany, on October 18, 1571. He studied at Rostock University and, from 1603 to 1610, taught in Amsterdam. In 1612 he presented a famous *Memorandum* (Memorial) at the election of the Holy Roman Emperor in Frankfurt, in which he offered to show how "Hebrew, Greek, Latin and other languages may be easily learned and disseminated, even in a short space of time, both to young and old." From 1614 to 1622, Ratke worked – less than successfully, it must be said – on innovative school projects in Augsburg, Köthen, and Magdeburg; from 1622 onward, he concentrated on his encyclopedic program. He died in Erfurt on April 27, 1635.

Ratke's program was dictated by his encyclopedic concept of education, which he saw as a solution to the social and political problems associated with the Thirty Years' War. It was probably conceived as a Lutheran alternative to the curricular program of the Roman Catholics and the Reformed Church.

Ratke realized early the importance of the native language as both a medium of instruction and a foundation for teaching other languages. He identified the same problem as Henry VIII and Mulcaster – the multiplicity and diversity of grammars and ways of teaching. But whereas Henry prohibited the use of all grammars in schools except one (Lily and Colet,

1549), Ratke refashioned the *harmonia linguarum* into a *harmonia didactica,* to mean that no part of a discipline should conflict with any other. A unified grammatical terminology over all the languages taught was the logical outcome.

Ratke's writings include a set of small universal grammars for five languages, printed in Köthen, and uniform in terminology, classification, scope, size and type. Each volume consists of a universal grammar written on and in the language concerned, and a section 'Special Properties,' detailing its attributes and values.

Although Ratke's program was only fragmentarily realized, the logic of his scheme made him an important innovator in many areas to do with language. In particular, Ratke's writings on German constitute significant landmarks in the history of German grammar writing (Ising, 1959), while his inductive approach through texts anticipated reforms in foreign-language teaching.

Raumer, Rudolf von (1815–1876)

M K C MacMahon, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Raumer is important as a representative of the transitional period in linguistic studies in Germany between the style of orthography-based philology associated with, for example, Jacob Grimm, and the work in the 1870s and thereafter of the Neogrammarians (*Junggrammatiker*), with their emphasis on the need to use knowledge of phonetics and modern dialectology for an understanding of the processes of linguistic change.

Raumer was born in Breslau (now Wrocław) on April 14, 1815. His parents were Karl Ludwig Georg von Raumer (1783–1873), a geologist and educational historian, and Friederike Reichardt (1790–1869). He died in Erlangen on August 30, 1876.

He attended secondary schools in Nürnberg and Erlangen. His university studies of classical and German philology were divided between Erlangen (1832–1834) and Göttingen (1834–1836). Among his teachers were the classical philologist and historian Friedrich Christoph Dahlmann (1785–1860) and Jacob Ludwig Carl Grimm (1785–1863). (Raumer's family and the brothers Grimm were friends.) He graduated from Erlangen in 1839, and for his *Habilitation* the following year he wrote a dissertation on Roman constitutional history (1840). He remained at Erlangen for the remainder of his life, teaching Germanic languages and history (particularly the history of Germany). From 1852 onward, he was Professor of German Language and Literature there.

Raumer's intellectual interests encompassed not only the history and contemporary state of German (e.g., 1848), but also religion and philosophy. Thus, another of his early works was a study of the

He attended secondary schools in Nürnberg and Erlangen. His university studies of classical and German philology were divided between Erlangen (1832–1834) and Göttingen (1834–1836). Among his teachers were the classical philologist and historian Friedrich Christoph Dahlmann (1785–1860) and Jacob Ludwig Carl Grimm (1785–1863). (Raumer's family and the brothers Grimm were friends.) He graduated from Erlangen in 1839, and for his *Habilitation* the following year he wrote a dissertation on Roman constitutional history (1840). He remained at Erlangen for the remainder of his life, teaching Germanic languages and history (particularly the history of Germany). From 1852 onward, he was Professor of German Language and Literature there.

Raumer's intellectual interests encompassed not only the history and contemporary state of German (e.g., 1848), but also religion and philosophy. Thus, another of his early works was a study of the

influence of Christianity on the literary texts of Old High German (1845). The period from Luther onward and the gradual emergence of a standardized form of German were of particular interest to him, resulting in several publications (e.g., 1856). His history of Germanic philology (1870), however, although dealing with the period from the Reformation to the 19th century, focuses primarily on the life and work of the brothers Grimm.

Raumer correctly identified the importance of a standardized orthography of German as one of the significant markers of the growing political unity of Germany over the centuries. The later formal codification of German orthography in 1880 was based mainly on the proposals that he had put forward (1876a).

He was the first of the relatively few 19th-century comparative linguists to consider the question of a possible relationship between Indo–European and Semitic, and argued, from admittedly a limited set of data, that there was some evidence to indicate a common ancestor for both language families (see particularly 1864, 1876b).

Unlike his teacher Jacob Grimm and many other linguists of the first half of the 19th century, Raumer recognized the need to use insights from phonetics in evaluating evidence for sound changes – hence, the importance in historiographical terms of his very first publication, on aspiration and sound change (1837). This is a farsighted account of how a phonetic, rather than simply an orthographic, perspective can elucidate questions about the nature of sounds at earlier periods in a language. Much of his argument is based on data from Sanskrit and Classical Greek.

Raymundus Lullus (ca. 1235–1315)

C Neis, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

[Ramón Lull/Llull] (**Figure 1**) was born in Palma, in Majorca, between 1232 and 1236, and died in Tunis in 1315. The *doctor illuminatus* was a philosopher, poet, and theologian mainly concerned with the conversion of the infidels and with the symbolic permutations of his *Ars Generalis Ultima* (*Ars Magna*), which he considered as a way of finding truth. Lull's *Ars magna* influenced the philosophy of Cusanus, was later discussed by Leibniz in his *Dissertatio de arte combinatoria* (1666), and was extended by Athanasius Kircher. Lull is also known as the first medieval philosopher who wrote in the vernacular (Catalan), thus even preceding Dante or Meister Eckhart.

Lull was born into a wealthy family that was well-acquainted with court life. Until the age of 30, he lived hedonistically as a courtier of King James of Aragon. When he was 30, a vision of the crucified Christ compelled him to leave his family to become a hermit and finally a tertiary of the Order of St. Francis. As a result of his conversion, Lull decided to pursue three principal aims: (1) becoming a missionary and accepting martyrdom, (2) writing a book to convert the infidels, (3) founding monasteries in which the languages of the infidels were to be taught for missionary purposes. Having spent his youth in

Raymundus Lullus (ca. 1235–1315)

C Neis, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

[Ramón Lull/Llull] (Figure 1) was born in Palma, in Majorca, between 1232 and 1236, and died in Tunis in 1315. The *doctor illuminatus* was a philosopher, poet, and theologian mainly concerned with the conversion of the infidels and with the symbolic permutations of his *Ars Generalis Ultima* (*Ars Magna*), which he considered as a way of finding truth. Lull's *Ars magna* influenced the philosophy of Cusanus, was later discussed by Leibniz in his *Dissertatio de arte combinatoria* (1666), and was extended by Athanasius Kircher. Lull is also known as the first medieval philosopher who wrote in the vernacular (Catalan), thus even preceding Dante or Meister Eckhart.

Lull was born into a wealthy family that was well-acquainted with court life. Until the age of 30, he lived hedonistically as a courtier of King James of Aragon. When he was 30, a vision of the crucified Christ compelled him to leave his family to become a hermit and finally a tertiary of the Order of St. Francis. As a result of his conversion, Lull decided to pursue three principal aims: (1) becoming a missionary and accepting martyrdom, (2) writing a book to convert the infidels, (3) founding monasteries in which the languages of the infidels were to be taught for missionary purposes. Having spent his youth in

Figure 1 Raymundus Lullus. Painted by Klause Froese, Berlin, 2004. Reproduced with permisssion.

a land where three religions converged (Christianity, Islam, and Judaism), Lull seemed to be the right person for this task. But being a gifted autodidact rather than a scholar, Lull focused on learning Latin and Arabic for almost a decade. At the age of 40, a divine illumination at Mount Randa (Majorca) ordered him to write a book against the errors of the infidels; this order was accomplished by writing the *Ars magna*, the most outstanding of Lull's 292 works. The *Ars Magna* is similar to a logical 'machine,' in which subjects and predicates of theological propositions are arranged in geometrical figures. By different forms of permutations, it is possible to gain affirmative or negative propositions and to have insight into the true nature of things. This combinatorial system, which included concepts, figures, and their permutations, was much inspired by Cabbalistic mysticism; it was also close to Galenus' conception of the four temperaments and to his astrology. In many of his treatises, Lull tried to apply his *Ars magna* to a huge variety of topics, such as philosophy, theology, law, medicine, physics, astrology, astronomy, and so forth. Since his illumination at Mount Randa, Lull had been traveling across Europe to propagate his *Ars* and to pursue his missionary activities. On his last sojourn in Tunisia, he was first sentenced to death and then banished. Legend has it that he was even lapidated. Lull died on a ship sailing from Northern Africa back to Majorca.

Although Lullism attracted an enthusiastic following for several centuries, it was also criticized for its sterility, e.g., by Swift in *Gulliver's travels*. Nevertheless, Lullism's deep impact on universal language projects is undeniable.

Reading and Multiliteracy

B Street, King's College, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A rich vein of articles and books has recently offered new perspectives on reading and literacy, invoking such terms as 'multiliteracies' and 'multiple literacies.' In this piece, I will signal some of the debates and concepts in this emerging field, with particular reference to New Literacy Studies (NLS), both in terms of theoretical perspectives and of their implications in schooled contexts, as theorists and practitioners address the tensions and possibilities that arise when students and teachers apply such innovations to curricula and classrooms. While 'reading' has generally been seen in educational contexts as about

Figure 1 Raymundus Lullus. Painted by Klause Froese, Berlin, 2004. Reproduced with permisssion.

a land where three religions converged (Christianity, Islam, and Judaism), Lull seemed to be the right person for this task. Reading and Multiliteracy

B Street, King's College, London, UK

A rich vein of articles and books has recently offered new perspectives on reading and literacy, invoking such terms as 'multiliteracies' and 'multiple literacies.' In this piece, I will signal some of the debates and concepts in this emerging field, with particular reference to New Literacy Studies (NLS), both in terms of theoretical perspectives and of their implications in schooled contexts, as theorists and practitioners address the tensions and possibilities that arise when students and teachers apply such innovations to curricula and classrooms. While 'reading' has generally been seen in educational contexts as about

decoding and much of the policy literature follows this line (cf. Snow, 1998), those researching literacy from a social practice perspective offer a broader interpretation of reading as well as of literacy that has profound implications for classroom practice.

Such reconceptualization begins from the problematizing of what counts as literacy at any time and place and asks 'whose literacies' are dominant and whose are marginalized or resistant. This query entails the recognition of multiple literacies, varying according to time and space but also contested in relations of power. To address these issues ethnographically, literacy researchers have focused on 'literacy events' and literacy practices,' the latter representing an attempt to handle the events and the patterns of activity around literacy but to **link** them to something broader of a cultural and social kind: part of that broadening involves attending to the fact that in a literacy event, we have brought to it concepts, social models regarding what the nature of this practice is and that make it work and give it meaning. This reconceptualizing of literacy has produced a wealth of 'ethnographies of literacy' (cf. Street, 1984, 2001; Barton, 2000; Baynham, 2004). The strength and significance of this approach and this considerable literature is attested by a recent spate of critical accounts that have addressed some of the problems that they raise, both in general and, more specifically, for educational applications.

An apt place to begin is with the contestations over the terms 'multiple literacies' and 'multiliteracies.' The notion of multiple literacies was coined in the early 1980s (Street, 1984) in order to make a contrast with a reified autonomous notion that dominated the field at that time, which assumed that there was only one thing called 'literacy' – which had a big 'L' and a little 'y': which was singular and autonomous in the sense that it was a factor that independently had effects on other things. The idea of multiple literacies, then, was an important construct in challenging that autonomous singular literacy: literacies vary according to cultural contexts and uses and what is taught in schools as 'the' literacy is only one variety among many.

The concept of multiliteracies that has been put forward by the 'New London Group' (NLG) (Cope and Kalanztis, 2000) refers not to multiple literacies, associated with different cultures or contexts, but to multiple forms of literacy associated with different channels or modes, such as computer literacy or visual literacy. Kress (1997), a member of the NLG, has criticized the further extensions of multiliteracy into, for instance, political literacy, or emotional literacy, thereby using the term as a metaphor for competence. The NLG are more interested in channels and modes of communication that can be referred to as 'literacies.' For Kress, multiliteracy signals a new world in which the reading and writing practices of literacy are only one part of what people are going to have to learn in order to be 'literate' (Kress and van Leeuwen, 1990). They are going to have learn to handle the icons and the signs, the Word for Windows package with all its combinations of signs, symbols, boundaries, pictures, words, texts, images, etc. The extreme version of this position is the notion of 'the end of language' – that somehow we are no longer talking about language in its rather traditional notion of grammar, lexicon, and semantics, but rather semiotic systems that cut across reading, writing, speech, into all these other semiotic forms of communication. This collection, then, is what is signaled by the term 'multiliteracies': a rather different approach from that entailed by the 'multiple literacies' view outlined above.

These approaches are currently being debated not only in terms of the boundaries of the concepts but also in terms of broader theoretical and methodological issues. In terms of theory, for instance, Brandt (2002) recently commented on 'the limits of the local' evident, she believes, in the ethnographic approach to multiple literacies. She argues that NLS ought to be more prepared to take account of the relatively 'autonomous' features of literacy without succumbing to the autonomous model with its well-documented flaws: this approach would involve, for instance, recognizing the extent to which literacy does often come to 'local' situations from outside and brings with it both skills and meanings that are larger than the emic perspective favored by NLS can always detect. This recognition, of course, is exactly what many educationalists would argue regarding the relationship between local literacy practices and those of the school. Likewise, Collins and Blot (2002) were concerned that, while NLS has generated a powerful series of ethnographies of literacy, there is a danger of simply piling up more descriptions of local literacies without addressing more general questions of both theory and practice. They proposed the terms 'texts power and identities' as a basis for comparative generalization, building on the descriptive capacity of the lenses offered by NLS to engender a more powerful set of generalizations about the uses and meanings of literacy practices. Those lenses were themselves sharpened by a number of contributors to an edited volume *Situated literacies* (Barton *et al.*, 2000). Gee, for instance, located the situated approach to literacies in relation to broader movements towards a 'social turn' that he sees as a challenge to the behaviorism and individualism that NLS has also pursued. Maybin, in the same volume, also links NLS to wider strands of social-critical

work, offering a way of linking Foucauldian notions of Discourse, Bakhtinian notions of intertextuality, and work in Critical Discourse Analysis with the recognition from NLS of "the articulation of different discourses [as] centrally and dynamically interwoven in people's everyday literacy activities." Bartlett and Holland (2002) likewise proposed an expanded conception of the 'space of literacy practices,' drawing upon innovations in the cultural school of psychology, sociocultural history, and social practice theory. They are particularly concerned to harness NLS to broader concerns with identity and suggest three concepts: figured world, artifacts, and identities in practice. As with the other papers and books, they build these extensions and developments upon the basic tenets of NLS, using ethnographic case studies of literacy in practice.

Another update and extension of NLS is to be found in Hornberger's edited volume (2002) in which authors attempt to apply her conception of the 'continua of biliteracy' to actual uses of reading and writing in different multilingual settings: 'biliteracy' is defined as "any and all instances in which communication occurs in two (or more) languages in or around writing" and is described in terms of four nested sets of intersecting continua characterizing the contexts, media, content, and development of biliteracy. A number of the authors, as in the Martin-Jones and Jones (2001) book, drew out the links of NLS to such multilingual settings. Peter Freebody's recent account of the different ways in which 'Critical Literacy' has been construed (Freebody, forthcoming) offered a further, critical perspective on NLS and its implications for education. He argued that the meanings of CL vary according to both "focus and method of study on the one hand and, on the other, the disciplines that have developed these approaches." Thus:

- Linguists have generally taken the text as a semiotically structured object, to be the prime unit of focus of critical literacy;
- Sociologists have generally focused on how language uses signal as the operation of social formations such as race, gender, and class, and how these formations in turn give shape to how we read, write, look, talk, and listen; and
- Anthropologists have taken cultural practices and the ways that different literate representations variously implicate and afford these.

Being rooted in anthropological approaches, although perhaps recently focused more in ethnographic methods from a range of sources, New Literacy Studies can be seen to focus more on practices than on texts and more on fine-tuned processes of identity construction than on gross categories of class, race, and gender. However, all three approaches would probably agree with Freebody's general characterization of CL as concerned "with giving access to texts, transforming sociopolitical processes and" – most crucially for NLS – "developing the practical understanding that people are educated to become variously the objects and subjects (both the topics of and the readers and writers) of a selected tradition of representing reality in public and official forms." How such traditions are constructed and reproduced and how individuals and social groups are inserted into them is a central focus of NLS – taking nothing for granted with respect to literacy and the social practices with which it becomes associated.

The effects of these critical engagements is that NLS is now going through a productive stage of theory building that first establishes and consolidates many of the earlier insights and empirical work, and second builds a broader and perhaps less beleaguered field of study that can appeal beyond the specific interests of ethnographers on the one hand and educationalists on the other, to those engaged in more general issues of identity, power, and textuality. The next stage of work in this area, then, is to move beyond simply theoretical critiques of the autonomous model of literacy and to develop positive proposals for interventions in teaching, curriculum, measurement criteria, and teacher education in both the formal and informal sectors, based upon these principles. It will be at this stage that the theoretical perspectives brought together in the 'New Literacy Studies' will face their sternest test: that of their practical applications to mainstream education. In a recent edited volume (Street, 2005), a number of authors took on this challenge and attempted to follow through such practical applications of the NLS approach, in terms of the links between such theoretical debate and the work of teachers in school addressing literacy issues. Likewise, Hull and Schultz (2001) built upon the foundational descriptions of out-of-school literacy events and practices developed within NLS, to return the gaze back to the relations between in and out of school, so that NLS is not seen simply as 'antischool' or as interested only in small scale literacies of resistance. They want to use the understandings of especially children's emerging experiences with literacy in their own cultural milieus to address broader educational questions about learning of literacy and of switching between the literacy practices required in different contexts. This issue was also addressed in current research by Baker, Street, and others applying literacy theory to the understanding of numeracy practices in and out of school (Baker and Street, 2004; Baynham and Baker, 2002).

Meanwhile, Larson's edited volume (2001) addressed the relationship between current policy initiatives that stress a more decontextualized view of literacy and the approaches indicated here, including NLS and 'critical' perspectives: the authors demonstrated the problems with the dominant narrow approach and attempted to construct more meaningful solutions. This theme was developed further in a forthcoming volume, *Framing literacies* (forthcoming), in which Larson and Marsh attempted to reconnect what we know about literacy learning to what we do. The book took three prominent theoretical frameworks, New Literacy Studies, Critical Literacy, and Sociocultural Theory, and illustrated what these frameworks look like in real case examples, articulating how the frameworks discussed work together to construct rich and complex contexts for literacy learning and progressive frameworks for research. Another volume in this genre, edited by Rowsell and Pahl (forthcoming), also attempted to make links explicitly between theory and educational practice. At a theoretical level, they attempted to combine the multiliteracies and the multiple literacies positions: "To meet the demands of our changing communicational landscape, we need to adjust our notion of literacy and its implications on how we produce texts in multiple settings, at different times, by different sets of actors." At the same time, they want to follow through the implications of this production for pedagogy and curriculum, and the authors in their volume provided examples of actual classroom practice where such shifts can be identified. The same two authors (Pahl and Rowsell, 2005) have also written a book for classroom teachers offering a practical guide to applying New Literacy Studies within primary, secondary, and family literacy contexts. It aimed to offer ways to rethink, redefine, and redesign language and literacy in the classroom to meet the contemporary needs and skills of students.

All of these initiatives, then, make considerable demands on both theorists and practitioners in the area of language and education in general and of literacy and reading in particular, challenging dominant views of each term and its applications. From this perspective, reading is now located in the broader field of literacies, and the understanding of literacies is in turn contested between approaches from ethnography, critical theory, and sociocultural views of language and learning. Whichever position one takes in this fast moving field, it will no longer be possible to envisage either reading or literacy in the simple, unidimensional ways that have dominated schooling until now.

Reading Processes in Adults

K Rayner and B Juhasz, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

To most adults, reading seems like a simple task. However, there are many different component processes involved in reading which make it quite a complex skill. In order to understand written text, such as a short story, letters must be identified, words must be recognized and assigned meaning, the words must be strung together to form the meaning of the sentence, and the sentence must be understood in the context of all of the other sentences that have occurred before it in the text. Therefore, although reading seems quite easy to us, it is because we have had much practice at all of the various components involved in reading. The story is very different for beginning readers and people with reading disabilities.

All of the components involved in reading are important to investigate in order to understand how the process works and how the skill develops. For example, many researchers are interested in the processes involved in word recognition. They therefore may examine how the letters (orthography), sounds (phonology), or meaning (semantics) of words contributes to the reading process. Likewise, other researchers study how sentences are processed or how a written discourse is understood. Many of the important components of reading and reading comprehension are addressed in other articles in this encyclopedia. By understanding the details associated with each component, a clear picture of the processes involved in reading begins to emerge. It is therefore important to understand reading processes in adults for the sake of understanding how the complex processes that make up reading are coordinated. A pioneer in reading research, E. B. Huey (1908), once remarked that understanding what skilled readers do when they read could easily represent a major achievement in psychological science. But it is also important to understand what skilled readers do so that what they do can be used to inform the teaching of reading to children and people with various reading disabilities (see Rayner *et al*., 2001, 2002).

Experimental Tasks and Reading

There are many experimental tasks available to researchers to study the different components involved in reading. For word recognition, researchers often use tasks that present a word in isolation on a computer screen and require a participant to make some type of response. Three such tasks will be briefly described. In the lexical decision task, letter strings are presented and participants must decide whether or not the letter string makes a word in their language. The time it takes participants to make their decision, and also the percentage of errors that they make, are then analyzed as a function of the variables being manipulated in the study. In a naming task, participants are presented with words and are asked to name them as quickly as possible, and the latency to name the word is recorded as the dependent measure. Also, semantic categorization tasks are sometimes used. In this task, a participant must say whether an exemplar (such as *shirt*) belongs to a particular category (such as *clothing*). A major criticism of these types of task is that the degree to which the tasks approximate normal reading can be questioned. When people read text silently to themselves, they do not encounter words out of context and they do not have to make a response to a word; they simply have to read it and understand what it means.

If a researcher is interested in studying how sentences are processed, they use other types of task. For example, participants might be presented with a sentence and be asked to simply read it and sometimes answer questions about it. The sentence may be presented all at once, in smaller subsections (such as a clause or phrase), or word by word. The presentation of the words in the sentence may be controlled by the participant (self-paced reading) or controlled by the experimenter (rapid serial visual presentation or RSVP). Researchers examining the processes involved in understanding longer texts tend to use similar methods. As with the tasks above, there are criticisms

To most adults, reading seems like a simple task. However, there are many different component processes involved in reading which make it quite a complex skill. In order to understand written text, such as a short story, letters must be identified, words must be recognized and assigned meaning, the words must be strung together to form the meaning of the sentence, and the sentence must be understood in the context of all of the other sentences that have occurred before it in the text. Therefore, although reading seems quite easy to us, it is because we have had much practice at all of the various components involved in reading. The story is very different for beginning readers and people with reading disabilities.

All of the components involved in reading are important to investigate in order to understand how the process works and how the skill develops. For example, many researchers are interested in the processes involved in word recognition. They therefore may examine how the letters (orthography), sounds (phonology), or meaning (semantics) of words contributes to the reading process. Likewise, other researchers study how sentences are processed or how a written discourse is understood. Many of the important components of reading and reading comprehension are addressed in other articles in this encyclopedia. By understanding the details associated with each component, a clear picture of the processes involved in reading begins to emerge. It is therefore important to understand reading processes in adults for the sake of understanding how the complex processes that make up reading are coordinated. A pioneer in reading research, E. B. Huey (1908), once remarked that understanding what skilled readers do when they read could easily represent a major achievement in psychological science. But it is also important to understand what skilled readers do so that what they do can be used to inform the teaching of reading to children and people with various reading disabilities (see Rayner *et al*., 2001, 2002).

Experimental Tasks and Reading

There are many experimental tasks available to researchers to study the different components involved in reading. For word recognition, researchers often use tasks that present a word in isolation on a computer screen and require a participant to make some type of response. Three such tasks will be briefly described. In the lexical decision task, letter strings are presented and participants must decide whether or not the letter string makes a word in their language. The time it takes participants to make their decision, and also the percentage of errors that they make, are then analyzed as a function of the variables being manipulated in the study. In a naming task, participants are presented with words and are asked to name them as quickly as possible, and the latency to name the word is recorded as the dependent measure. Also, semantic categorization tasks are sometimes used. In this task, a participant must say whether an exemplar (such as *shirt*) belongs to a particular category (such as *clothing*). A major criticism of these types of task is that the degree to which the tasks approximate normal reading can be questioned. When people read text silently to themselves, they do not encounter words out of context and they do not have to make a response to a word; they simply have to read it and understand what it means.

If a researcher is interested in studying how sentences are processed, they use other types of task. For example, participants might be presented with a sentence and be asked to simply read it and sometimes answer questions about it. The sentence may be presented all at once, in smaller subsections (such as a clause or phrase), or word by word. The presentation of the words in the sentence may be controlled by the participant (self-paced reading) or controlled by the experimenter (rapid serial visual presentation or RSVP). Researchers examining the processes involved in understanding longer texts tend to use similar methods. As with the tasks above, there are criticisms

of these techniques as well. For example, in most of these tasks once a word, phrase, or sentence has been read, it disappears from the screen. This is unlike normal reading, where people can reread text at their own rate.

By recording readers' eye movements as they read sentences or short texts, all of the processes involved in reading can be examined in a more natural way. Eye movements are recorded through the use of an eye tracker which interfaces with a computer. Participants read material on a computer screen, as they would normally read. Sometimes, they are asked questions about the text. Eye trackers come in all varieties. Some of them use an infrared beam of light to record the eye's position in the text. These eye trackers are very precise and require a participant's head to remain very still. Newer eye trackers record readers' eye movements with a small camera attached to a cap or headband that the reader wears. By recording readers' eye movements, it is possible to study all aspects of reading, including word recognition, sentence processing, and discourse processing. The eye movement literature has provided a wealth of knowledge regarding how reading occurs. The rest of this entry will be devoted to what we have learned about reading from studying eye movements.

Figure 1 Eye movement data from three different college-age readers on the same sentence. For each reader, the asterisk indicates eye position. Directly underneath the asterisk is the fixation sequence. Underneath the sequence number is the fixation duration for that particular fixation.

Basic Facts about Eye Movements in Reading

In order to understand how reading occurs, it is important to explore how eye movements contribute to the reading process. While people have the impression that their eyes move continuously through text, only pausing on difficult parts occasionally, this is not the case. Instead, the eyes alternate between a series of pauses (called fixations) and eye movements (called saccades) while reading. On average, fixations last roughly 200 to 250 ms, although there is variability. Also, the average saccade length when reading English is roughly six to nine character spaces and lasts approximately 20 to 50 ms. Vision is mostly suppressed during saccades so information is extracted only during fixations during reading (see Rayner, 1998 for more details).

During normal reading, people move forward in text 85% to 90% of the time. The remaining 10% to 15% of the time is devoted to regressions, that is, moving the eyes back in the text. To date, the factors that lead to regressions are not very well understood. However, it is clear that regressions can be caused either by comprehension difficulties or error in where the eyes landed (called oculomotor error). One special type of regression is called a return sweep. This is a right-to-left eye movement (when reading English) that occurs when the eyes move from the end of one line of text to the beginning of the next line of text (Rayner, 1998).

As mentioned above, there is variability in the average length of fixations (called fixation durations), saccade size, and regression rates. As the difficulty of the reading material increases, saccade size tends to decrease, fixation durations increase, and more regressions are made. The skill of the reader also affects eye movement characteristics, with less skilled readers showing longer fixation durations, more regressions, and shorter saccades.

There is also variability in these measures within a reader. Figure 1 illustrates this point by showing the eye movement patterns on a single sentence for three college-age readers. In this experiment, participants were simply asked to read sentences for meaning and answer a question on them occasionally. For a person reading a single sentence, it is not uncommon to see fixation durations from less than 100 ms to over 450 ms. Much of this variability is due to how easy or difficult the currently fixated word is to recognize. For example, if a word is not familiar (e.g., *steward*), people will fixate it longer than if a word is very familiar (e.g., *student*). In addition, saccade sizes can range from one

character space to over 14 character spaces. However, long saccade sizes typically only follow regressions (see Rayner, 1998 for more information).

Most of the research to date on eye movements during reading has been done with English and other alphabetic languages. The kinds of summary statements that we made above generally hold true across the different languages. However, other writing systems obviously exist that are basically nonalphabetical in nature (such as Japanese and Chinese). There is now a lot of interest in crosscultural differences in how eye movements interact with the specific type of writing system. One apparent generalization is that the nature of the writing system obviously has big effects on the eye movements. For example, Chinese readers don't move their eyes as far in each saccade (so the forward saccade is about 2.3 characters for Chinese) as do readers of alphabetic languages. Readers of Hebrew also don't move their eyes forward (where forward means to the left since they read from right to left) as far as English readers do. This again falls out from the fact that Hebrew is more densely represented on the page (so it takes fewer letters to write a sentence in Hebrew because, for example, the vowels are systematically deleted in the orthography for skilled readers). Nevertheless, it appears to be the case that when characters or words are converted into 'idea' units, the amount of time it takes to read a given sentence is relatively constant across languages. Our expectation is that the next few years will see a considerable increase in the number of crosscultural studies examining the eye movements of skilled readers in different countries.

Measuring Cognitive Processing during Reading

There are a number of measures that can be obtained from the eye movement record. Some of these have become standard. First, it is important to point out that depending on the purpose of the experiment (i.e., whether it is investigating word recognition, sentence processing, or discourse processes), the regions of interest may vary. Many researchers use eye movements to examine how individual words are recognized. Thus, in these studies the word is the region of interest. When this is the case, the typical measures are as follows:

- First fixation duration: The duration of the first fixation on the word irrespective of how many fixations the word receives.
- Single fixation duration: The first fixation duration on the word if and only if the word received a single fixation the first time it was read.
- Gaze duration: The sum of all fixations on a word before the reader moves their eyes from the word. This is probably the most reported measure.
- Go-past time: The sum of all fixations on a word and the sum of any fixations spent rereading the text prior to the word before the reader moves their eyes to the right of the word.
- Total fixation duration: The sum of all fixation durations on a word, including time spent rereading the word after the reader left the word.

In addition to these measures, other measures such as the probability of skipping a word are often reported. In order to get a good idea of what is happening in reading, as many measures as possible are examined in the eye movement record. Different measures can highlight the differing time course of certain variables (for example, an effect may have an early but lasting effect and influence all measures, or it may be a later effect and only show up in total fixation duration when rereading is taken into account). While these measures deal with a single word as the region of interest, analogous measures also exist for cases when the region of interest is many words.

The Perceptual Span in Reading and the Use of Parafoveal Information

When we read, not all letters and words on a line of text can be seen with the same clarity. A line of text can be divided into three regions based on acuity limitations. The foveal region comprises 1° to the left and right of fixation and has the best acuity; here letters can be identified easily. The parafoveal region comprises the 4° to the left and right of the foveal region. In this region, acuity is not as good and it is more difficult to identify letters than when they are in the foveal region. Finally, the peripheral region is everything outside of the foveal and parafoveal regions. Acuity in this region is very poor (acuity differences are due to the anatomical make-up of the retina and the distribution of rods and cones). Thus, one of the main purposes of eye movements in reading is to bring information (i.e., the words being read) inside the foveal region, where it can be most easily identified.

Much research has been devoted to identifying how much information can be obtained on a single fixation during reading (i.e., the perceptual span in reading). In order to answer this question, techniques were invented in which experimenters could manipulate the amount of information available to the reader based on where the person was fixating (called the eye-contingent display change technique). Figure 2 Examples of three eye-contingent display techniques. In each panel, the asterisk indicates the eye position.

section, we will outline the techniques that have been used to address this question and then briefly summarize the main findings from experiments using these techniques.

Eye-Contingent Display Change Paradigms

There are three main types of eye-contingent display change techniques (see Figure 2 for examples). The first kind is called the moving window technique (McConkie and Rayner, 1975). In this paradigm, there is a window of text (the size of which is specified by the experimenter) around a person's fixation that is intact. The remaining text outside of the window is usually replaced by random letters or Xs. The window moves with the reader's eyes. If the window is large enough, the reader is not disturbed by the random letters outside of the moving window. Conversely, if the window is too small, the reader will be significantly slowed down by the lack of useful information outside of the moving window.

The foveal mask technique (Rayner and Bertera, 1979) is basically the opposite of the moving window. In this technique, wherever a reader fixates is replaced by a mask (usually of Xs). The text outside of this mask is intact. Therefore, with this technique, readers only have access to letters in their parafovea.

Finally, the most widely used eye-contingent display change technique is the boundary technique (Rayner, 1975). In this technique, there is an invisible boundary specified in the text. When the reader's eye crosses that boundary, a word (or nonword) that was originally displayed changes into a target word. Since the display change occurs during a saccade (when vision is suppressed), readers do not notice this change. The time spent reading the target word can be computed as a function of the type of preview that was available. By manipulating the type of preview, experimenters can explore what type of information readers extract from their parafovea.

Findings from the Eye-Contingent Display Paradigms

Studies using the eye-contingent display change techniques have demonstrated several findings about the perceptual span during reading. First, the perceptual span extends roughly 15 character spaces to the right of fixation (see, e.g., McConkie and Rayner, 1975; Rayner and Bertera, 1979). The perceptual span is also asymmetric, in that it extends further to the right than to the left. The perceptual span extends three or four character spaces to the left, which usually only comprises the beginning of the word being fixated (see, e.g., Rayner *et al.*, 1980a). Interestingly, this is only true for readers whose languages are printed from left to right. Readers of Hebrew (which is printed right to left) have the reverse asymmetry in

their perceptual span. Thus, it appears that the asymmetry is due to attention, as opposed to the visual system itself (Pollatsek *et al.*, 1981).

While the perceptual span extends 15 or so characters to the right of fixation, words cannot necessarily be identified that far out into the parafovea. Instead, studies suggest that the word identification span is roughly half the size (7 or 8 characters) of the perceptual span to the right of fixation (see, e.g., Underwood and McConkie, 1985). Outside of the word identification span, readers only gain rough information about letter shape and word length. Both the size of the perceptual span and the word identification span can be modulated by the text being read. For example, if the word that is fixated is difficult, less information about the parafoveal word is obtained (see, e.g., Henderson and Ferreira, 1990). In addition, the span varies based on the language that is being read. Readers of languages such as Chinese and Japanese have smaller spans (see, e.g., Ikeda and Saida, 1978) due to the fact that each character in these languages contains more information than in a language such as English.

Experiments using the boundary technique have shown that information gained about a word to the right of fixation (i.e., the parafoveal word) is subsequently used to speed identification of that word once it is fixated. Boundary change experiments have manipulated the similarity of the preview word and the subsequently fixated target word in order to identify what types of information are accessed from a parafoveal word. According to these experiments, information about the first few letters of an upcoming word is utilized during reading (see, e.g., Rayner *et al.*, 1980b). This information seems to be in the form of abstract letter codes, since changing the case of letters on each fixation does not significantly disrupt reading behavior (see, e.g., McConkie and Zola, 1979). Also, Pollatsek *et al.* (1992) found that phonological information is gained from the parafovea during reading. To date, no researcher using the boundary change technique has found evidence for parafoveal usage of morphological or partial semantic information (see, e.g., Lima, 1987; Rayner *et al.*, 1986). Note, however, that semantic information is sometimes obtained from the parafovea, as not all words are fixated. When words are skipped, their meaning was presumably accessed in the parafovea and no fixation was necessary on the word (short function words are skipped more often than content words).

Developmental Trends in Eye Movements

Table 1, which is a summary adapted from Rayner (1998), illustrates the developmental changes that take place in eye movement behavior during reading. It shows the average fixation durations, number of fixations per 100 words, and percentage of regressions made. As can be seen, as a reader becomes more skilled, they have shorter fixation durations, fewer fixations overall, and also more regressions. The lesser number of fixations is mostly due to the fact that readers are less likely to refixate words (i.e., make more than one fixation on a word) as they become more skilled. In addition, saccade length increases as beginning readers get more skilled (see Rayner, 1998 for more details). Rayner (1986) also demonstrated that the perceptual span of beginning readers is significantly smaller than that of skilled readers. Thus, beginning readers do not obtain as much information from parafoveal vision as skilled readers. This may be related to the fact that beginning readers undoubtedly find the text they are currently fixating difficult, and as mentioned above, less parafoveal information can be used, even by skilled readers, when the word currently being fixated is difficult (Henderson and Ferreira, 1990). Interestingly, it only takes roughly 1 year of reading education for beginning readers to show the asymmetry in their perceptual span that skilled readers show.

Table 1 Characteristic of eye movements during reading as a function of grade level

Grade level	*Fixation duration (ms)*	*Fixations per 100 words*	*Frequency of regressions %*
1	355	191	28
2	306	151	26
3	286	131	25
4	266	121	26
5	255	117	26
6	249	106	22
Adult	233	94	14

Models of Eye Movements during Reading

Since studying eye movements has been so important to understanding the process of reading, it is not surprising that there have been many attempts to model eye movements in reading. A thorough review of these models is not in the scope of this chapter (an interested reader should consult Reichle *et al.*, 2003). However, it should be noted that most models of eye movement control in reading can be broken into two general classes. One of these classes views eye movements in reading to be driven basically by low-level oculomotor factors while the other views eye movements as being primarily driven by cognitive factors.

So how do these models differ? There are two decisions that have to be made while reading. One decision is where the reader should fixate next and the other is when they should fixate next (i.e., when they should leave the currently fixated word). Proponents of both types of models agree that the where-decision is driven by low-level factors such as word length information. However, proponents of the oculomotor models believe that the when-decision is also driven by low-level factors, such as whether the fixation landed in a nonoptimal position on the word. On the other hand, proponents of the cognitive models believe that the when-decision is driven by the cognitive processing of the word that is currently being fixated. There is now much research that demonstrates how factors associated with the text being read (such as word familiarity, as mentioned above) significantly affect fixation duration. This lends support to the cognitive models of eye movements in reading.

Conclusions

In this article, we have primarily provided information regarding the importance of studying eye movements in understanding the reading process. By studying eye movements, researchers have demonstrated how important parafoveal information is to the reading process, the amount of information that can be processed at one time in reading, and changes in eye movements during development. Also, there is much evidence that supports the fact that variability in eye fixation in reading is due to the properties of the text that is currently being fixated. By designing clever experiments, eye movement research can elucidate what factors affect word recognition and the processing of sentences, and also how people process and represent information while reading. The knowledge that is gained by these types of experiment is useful in that it (1) provides information on how one of the most complex skills that humans have learned works, and (2) provides practical information on how to more effectively teach reading.

Reading Processes in Children

J Oakhill, University of Sussex, Brighton, UK
K Cain, University of Essex, Colchester, UK

© 2006 Elsevier Ltd. All rights reserved.

When people think about children's reading and reading acquisition, they usually think of learning to read words. However, the real purpose of reading lies in deriving meaning from the text, and this aspect of children's reading is covered later in this article. There is a large body of research into how children acquire reading skills, and this article is necessarily very selective.

The first section outlines the reading-related skills that children acquire early in their reading careers, and considers which, if any, of these skills are prerequisites for the development of reading. The second section gives an account of some important aspects of the development of reading skills, and in the final section comprehension is considered, both its normal development and comprehension difficulties. The majority of the research on children's reading and reading development concerns children's learning to read in an alphabetic orthography, usually English, and that bias is reflected in this article.

The Development of Word Reading

Ways of Reading Words

There are different ways in which words might be deciphered, and some or all of these ways might be used (to a greater or lesser extent) as children learn to read and, indeed, by skilled readers (see Ehri and Snowling, 2004). The first way – to *decode* words to sound by applying knowledge about how written symbols (*graphemes*) map onto spoken units (*phonemes*) – relies on the *alphabetic principle* of written English. Decoding requires that the reader first parse the written word into its constituent graphemes (which do not necessarily correspond to letters). This process is sometimes called segmentation. The phonemes that correspond to the graphemes then need to be allocated, and the resulting string of phonemes *blended* to produce the equivalent spoken word. One problem with decoding is that phonemes are not discrete entities (because of the issue of *coarticulation*), and so getting from a string of phonemes to the spoken word requires a leap of faith, or at least a little flexibility and imagination. Because phonemes cannot be said in isolation, only approximations to the underlying phonemes can be derived. Thus, the phonemes /c/ /a/ /t/ will never produce the word *cat*, however rapidly they are pronounced, without some distortion. Another issue, one that is particularly problematic in English because of its notorious irregularity, is that graphemes do not map onto phonemes in a regular and systematic manner. Nevertheless, English is not so irregular as is sometimes assumed, particularly when higher-order, context-specific rules about pronunciation are taken into account. For instance, the rule about the pronunciation of word-initial c is quite regular and depends on the vowel that follows. So, despite the apparent problems with the use of grapheme-to-phoneme correspondence rules, methods of teaching reading that are based on this principle – so-called *phonics* methods – have consistently been shown to outperform other methods (National Reading Panel, 2000). A more advanced form of decoding, one that blends into the next method of decoding we outline, is to consider larger chunks of words as the unit of analysis. Thus, a more mature reader who has greater orthographic knowledge (knowledge of spelling patterns) will be able to apprehend familiar clusters in words, such as typical verb endings (*-ed*, *-ing*), affixes and highly familiar spelling patterns (e.g., *ight*, *ake*).

The second way to decipher words is by *analogy* with other, already known words. Thus, if a reader knows the words *cake*, *bake*, and *lake*, he or she may well be able to infer the pronunciation of an unknown word, such as *fake*, by analogy between the *rimes* of these words. In single-syllable English words, the pronunciation of rimes is much more regular than that of phonemes, so attention to rime units can help during reading development, though there is considerable debate about the stage at which such units are helpful to children (see, e.g., Ehri and Robbins, 1992; Goswami, 1986).

A third way to decipher words is by *prediction from context*, perhaps with the help of some partial word cues, such as initial letter. Some authors have claimed that use of context is the main way of reading in adults, particularly in irregular orthographies, such as English, and is the way children learn to read (see, e.g., Goodman, 1976). Prediction, however, cannot account for how most words are read, because words cannot be guessed accurately even by skilled readers (for striking examples, see Gough and Wren, 1999). The available evidence suggests that contextual cues are more likely to be used by readers to monitor the process of reading (i.e., to correct errors after words have been 'recognized') than to play a significant role in initial word decoding.

A fourth way to read words (and one that is usually associated with skilled reading rather than developing reading) is to recognize the word 'by sight' or from

memory. This is often referred to as *sight word reading*. When words are very familiar, readers can recognize them at a glance, and the pronunciation and meaning of the word will immediately come to mind. However, as we shall see later, this way of reading does not imply that the word is recognized as an unanalyzed 'visual pattern.'

Stage and Phase Models of the Development of Reading

Various models have attempted to give an account of the stages or phases that children go through as they learn to read. In general, such models propose that the child progresses from reading words as unanalyzed wholes to taking more analytic approaches in which he or she uses grapheme-to-phoneme mappings and orthographic knowledge. For instance, an early model (Frith, 1985) proposed three stages:

1. A *logographic* stage, in which the child recognizes familiar words as visual patterns, using salient visual features. Untaught words cannot be identified but might be guessed from context.
2. An *alphabetic* stage, in which the child learns and uses grapheme-phoneme mappings to decipher unknown words and to read nonwords.
3. An *orthographic* stage, in which the child learns the conventions and higher-order rules of the orthography and identifies words by making use of orthographic units larger than graphemes, without recourse to grapheme-phoneme conversion.

Frith also applied her model to spelling development and to the understanding of dyslexia. She argued that different types of developmental dyslexia can be understood as arising because the children who have particular types of reading disability become 'arrested' at a certain stage of reading development.

More recent models of reading development have suggested that it should be viewed as the progression through overlapping phases, rather than discrete stages, and have also made more explicit the difference between early recognition of words as visual patterns and skilled 'sight word' recognition. Ehri (1999; for a summary, see Ehri and Snowling, 2004) proposed a phase theory to describe the progress of reading development. Ehri preferred the idea of a phase, rather than a stage, in reading development, because she regarded phases as less stringent ways of characterizing periods of development and also because her theory differed from stage theories in that overlap between phases was envisaged, rather than the sequential progression that is intrinsic to stage theories. Ehri distinguished between four phases in learning to read words: (a) a *prealphabetic* phase, (b) a *partial-alphabetic* phase, (c) a *full-alphabetic* phase, and (d) a *consolidated-alphabetic* phase. The prealphabetic phase characterizes the period when children have very little knowledge of the alphabetic system. Thus, they remember words by using salient visual cues, such as remembering the word yellow has 'two sticks in the middle,' or the sign for McDonald's has 'two arches and is red.' This phase is similar to Frith's logographic stage. In the partial-alphabetic phase, as the name suggests, children have some partial knowledge of the alphabetic principle and so will be able to use some of the letters in words – typically first letters – to help themselves remember the identity of those words. Because only partial cues are being used, a child in this stage might think that any short word beginning with the letter d says *dog* and will typically confuse similar words (e.g., *horse* and *house*). In the full-alphabetic phase, the reader will know the major grapheme-phoneme correspondences in the writing system and will also have developed a sufficient level of *phonemic awareness* to segment words into phoneme units (phoneme segmentation). As a result of these skills, the reader will be able to read new words by decoding them and will also have the ability to approximate the spelling of words. An important aspect of this phase is the child's developing ability to read independently – i.e., to translate unfamiliar printed words to their spoken equivalents by phonological recoding (or 'decoding'), rather than having to be told what they are. This important development has been referred to as a self-teaching mechanism (e.g., see Share, 2004). The idea behind this mechanism is that each successful identification of a new word provides the reader with the opportunity to acquire the word-specific orthographic information that is important in visual word recognition. In the consolidated-alphabetic phase, the child will have acquired knowledge of larger units and of context-dependent spelling patterns. In this phase, readers are able to use a variety of different strategies (including developmentally prior ones, such as using grapheme-phoneme correspondence rules) to decipher unfamiliar words. They will, for instance, be able to read words by analogy with other words, will be aware of familiar spelling patterns and their pronunciation (e.g., *wr-, thr-, -ight, -ing*), will know about exception words, such as *island*, *pint*, and *colonel*, and will be aware (at least implicitly) of contextual constraints on pronunciation of graphemes, such as the pronunciation of c depending on the vowel that follows (consider how you would pronounce the nonwords *cibe*, *cort*, *cyne*, and *culf*). In this phase, much of the knowledge is likely to come from experience of reading, rather than through explicit teaching.

In general, these levels are closely linked to age and years of schooling, but in principle they need not be. Children and even adults may fail to progress to the higher phases if they do not develop a good working knowledge of the alphabetic and orthographic principles of their language. More recently, Frith's idea that developmental disorders of reading arise because children get 'arrested' at an earlier stage of development has been shown to be too simplistic. It is more likely that a stage or phase theory will capture the *predominant* difficulties associated with particular types of developmental disorder. Reading disorders are outside the scope of this article, but further discussion of this topic can be found in Ehri and Snowling (2004).

One important thing to note about stage and phase models of reading is that the 'sight word' reading of the skilled reader is a far more sophisticated mechanism than the logographic reading of the beginning reader. The beginning reader will be able to recognize a restricted set of words by using limited cues, whereas the skilled sight word reader will have a wealth of information about a written word coming in simultaneously – information at many levels (graphemes, rimes, analogies, etc.). Neither is it the case that the decoding phase can be skipped. Some have suggested that decoding to sound is simply a distraction for the child and can even be harmful in the development of fluent word recognition. However, from a self-teaching perspective, decoding of words is crucial in order for the child to form well-specified and complete orthographic representations of words.

The way in which children approach initial reading is not likely to be invariant, and may depend crucially on how they are taught, on what skills they have available to them, and on what language they are learning to read in: for instance, children who begin reading with some phonological skills in place may not go through a logographic stage at all (see Stuart and Coltheart, 1988), and children who are learning to read in German (which is more orthographically transparent than English) may proceed more rapidly to the full-alphabetic phase (see, e.g., Wimmer and Hummer, 1990).

Reading Comprehension

The Development of Comprehension Skills

There is relatively little research on the development of children's reading comprehension and currently no developmental model of reading comprehension. In this section, we outline some of the important component skills for comprehension and how they develop (not necessarily in a reading context). A longer review of the development of comprehension and comprehension-related skills can be found in Oakhill and Cain (2003).

It seems reasonable to assume that once children have learned to decode with a reasonable level of efficiency, comprehension will follow automatically, since children learning to read have for some years been understanding the spoken language. In general, reading and listening comprehension are highly correlated, particularly when decoding differences are small (i.e., the correlation tends to increase with age, as children become more proficient decoders). However, Garton and Pratt (1998) have suggested that children's listening comprehension may not always be as good as it seems from their everyday spoken interactions. The context in which spoken language is understood provides many cues to meaning (e.g., facial expression, tone of voice and intonation patterns of the speaker, as well as gestures), and such factors may give the impression that a child's understanding of spoken language is better than it perhaps is.

Although there is usually a strong association between listening comprehension and reading comprehension (at least in older children and adults), this relation might arise because tests of listening comprehension usually involve oral presentations of passages designed for reading. There are reasons that beginner readers in particular might have comprehension problems that are specific to reading. First, written language typically makes use of syntactic constructions and vocabulary that may not be well-known to children from their spoken interactions (see, e.g., Scott, 2004). The 'language of books' is a specific language register with which children may not be familiar – particularly if they have not had many books read to them before and as they begin to read. In addition, written language demands the integration of information across extended tracts of discourse in a manner that spoken language usually does not (and, of course, the text cannot be interrogated in the way that an unclear speaker can). Second, young children may be so engrossed in the word-decoding aspect of reading that they do not have sufficient spare cognitive capacity to carry out comprehension processes. As children get older and their decoding skills improve, they are likely to have more resources to devote to comprehension. Indeed, it has been shown that in the later primary school years, comprehension ability replaces decoding ability as the most important predictor of overall reading level (Curtis, 1980). In the remainder of this section, consideration is given to comprehension processes where there is likely to be some overlap between written and spoken language understanding. It should be borne in mind, however, that some of the processes may be more

difficult to carry out in the case of written text, for the reasons given earlier.

Understanding a text can be viewed as a constructive process that results in a coherent and integrated representation of the state of affairs described: a representation that is often referred to as a *Mental Model* (e.g., Johnson-Laird, 1983) or a *Situation Model* (Kintsch, 1998). In order to construct such a representation, the reader needs to engage in a number of processes; thus, many different skills may contribute to text comprehension. The reader needs to derive and integrate the meanings of the individual words, sentences, and paragraphs. He or she also needs to identify the key ideas in or themes of the text. To understand a story, for instance, the main characters and their motives, and the plot of the story, need to be determined. Inferences must be made to fill in information that is left implicit in the text. In addition, skilled readers reflect on what they are reading – for example, what the main points are and whether or not the readers' emerging model of the text makes sense. By monitoring their comprehension in this way, readers can identify when they need to make an inference to fill in missing details and can take corrective action, such as rereading, when comprehension fails. In efficient text comprehension, many of these processes will be going on in parallel.

We next review work that has explored the development of three skills specifically associated with the construction of the meaning-based representation of a text – namely, inference making, metacognition and comprehension monitoring, and understanding text structure. One factor that we will consider in relation to the development of these three reading-related skills is working-memory capacity. Working memory refers to the system used to store and manipulate information simultaneously (Baddeley, 1986). Children's working-memory capacity increases with age, together with gains in text comprehension (for a review, see Cain, 2005). The cognitive resources available to readers will affect how well they can engage in the processes needed to set up and develop their representation of a text's meaning. Thus, working-memory capacity may be a limiting factor in the development of good text comprehension.

Inference Making The construction of a meaning-based representation of a text involves going beyond the literal content of the text through the generation of inferences to make links and to fill in missing details. Inference has many roles in comprehension: it can be used to establish referential coherence, causal antecedents to events, and characters' emotional reactions (see, e.g., Graesser *et al.*, 1994). In general, inferences can be distinguished into two main types: coherence and elaborative. Coherence inferences are necessary, in that they require that information explicitly provided in the text be integrated and/or that information from general knowledge be incorporated with information in the text itself, to establish local cohesion between adjacent clauses or to establish global coherence between different events, actions, and states in a text. Elaborative inferences embellish information in the text, but they are not strictly necessary to understanding. In effective and efficient comprehension, the emerging mental model of the text will be used to indicate where such gaps in comprehension occur and act as a signal to the reader that an inference is needed.

Developmental studies show that young children are able to make the same inferences as older ones. They are also sensitive to the necessity of the inference; for example, they do not make unlimited numbers of elaborative inferences, and they make a greater number of necessary inferences than purely elaborative ones. However, younger children do not make as many relevant inferences as older children.

Several factors may limit younger children's ability to generate inferences. Many inferences rely on knowledge of the world, and there is a good deal of evidence that prior knowledge influences both comprehension and memory for text in children. One possibility is that young children fail to generate inferences because they lack the relevant knowledge. In one study, however, it was shown that between 6 and 15 years of age, the ability to make inferences developed *independently* of the influence of knowledge (Barnes *et al.*, 1996). Thus, young children's difficulties with inference making cannot be attributed solely to general knowledge deficits. Strategic reading behavior may also play a role in the generation of inferences. Young children may lack the knowledge about how and when to make inferences. Indeed, children can be trained to use cues and to generate questions that promote the production of crucial inferences, which, in turn, facilitates their comprehension of the text. A third possibility is that young children's inference-making skills are limited by their developing working-memory capacity. The available processing capacity of this memory system will limit the ability to integrate information within the text and to incorporate general knowledge to fill out implicit details.

An important issue is whether inferences are generated as the text is read or later, perhaps when prompted by a question. Most research on children's inference making has assessed their ability by use of memory measures, such as question-answering or recognition tests. As a result, we know little about which inferences children make on-line – *as they are*

reading – and how age and reading ability might affect this process. The available data suggest that by the age of 9 years, children slow down while reading key sentences that require an inference to be made – an indication that they are engaging in inferential processing during reading.

Metacognition Metacognition about reading concerns knowledge about the purpose, goals, and processes of reading and the regulation of reading. An overview of different types of metacognitive skills, and their relation to reading ability, can be found in Westby (2004).

Knowledge about reading. A popular way to assess children's knowledge about reading is simply to ask them questions, sometimes by describing hypothetical situations that they may have experienced and asking them what they would do. When interviewed, young children often demonstrate a lack of awareness that they need to make sense of the text and are more likely to report that reading is about 'getting the words right.' It is not surprising that beginner readers place a greater emphasis on word-reading accuracy than comprehension, because to them the former is likely to be the more salient and/or emphasized feature of reading. Thus, young children's reading ability might be limited in part because their view of the purpose of reading is different from that of older children.

Comprehension monitoring. Comprehension monitoring concerns the understanding of connected prose. It is usually assessed by a reader's ability to detect inconsistencies in text, such as made-up words, scrambled sentences, contradictory sentences, or statements that conflict with external information (world knowledge). These error-detection tasks require readers to evaluate their understanding of the text. Although there is a general tendency for comprehension monitoring to improve with age, the extent to which it is demonstrated can be affected quite dramatically by aspects of the task.

Younger children are often unable to detect that crucial information is missing from a text and do not seem to realize when a text does not make sense. However, they are able to detect some errors. For example, young children are better at detecting lexical inconsistencies – made-up words – than internal inconsistencies, where two pieces of information in the text contradict each other. The instructions given to the child can also influence performance. Children are more likely to report problems when they are forewarned of them or if the task is given gamelike qualities (that is, the children are asked to pretend they are editors or detectives). They are also more likely to report a lack of understanding when the criteria are made explicit, for instance when they are required to assess whether or not instructions work compared with when they have to select their own criteria, as is the case when they are looking for inconsistencies in text. Thus, the standards used by children to detect errors improve with age.

Age-related improvements on error-detection tasks may also be related to children's developing information-processing capabilities. Their monitoring difficulties are more pronounced when the anomalous pieces of information are nonadjacent and have to be integrated across several lines of text; this indicates that working-memory capacity may play a role. In addition, effective comprehension monitoring cannot take place unless the reader has acquired the ability to integrate propositions to construct a coherent representation of a text. Thus, successful comprehension monitoring may be linked to good inference-making skills and vice versa.

Self-regulation of reading. A skilled reader needs knowledge about reading strategies: how to read for different goals and purposes. In contrast to young children, older readers appreciate that someone might read a story differently if their goal is to remember the story word for word than if the goal is to remember its meaning. Readers also need to possess the appropriate strategic knowledge so that they can take corrective action when failures in comprehension are detected. Knowledge about effective repair strategies improves with age. Thus, young children's reading ability might be limited by their restricted knowledge about the goals and purposes of reading and about specific reading strategies.

Understanding Text Structure A central element in comprehension is understanding how the ideas in a text are related to produce an interpretation of the text as whole. Explicit awareness about text structure and the expectations engendered by certain common features of text may be useful aids for readers, helping them to invoke relevant background information and schemas to facilitate the integration of the different ideas in a text. This integration will depend on many skills and abilities, such as inference making, but an important one is the ability to appreciate which are the main ideas in a text (what it is about) and to understand how it is structured. The majority of research with developing readers has focused on understanding of narrative structure, because this is the form of text that young readers are most familiar with.

The ability to identify the main ideas in a text has been described as the "essence of reading comprehension." Young readers have difficulties in recognizing the central theme or main ideas, and even 12- and

13-year-olds sometimes find it hard to discriminate between relevant and irrelevant detail in a text. As children develop, not only do they get better at selecting the main point in a story; they also change their minds about what sort of information is most important. In addition, they expect certain types of information to occur in stories, and they add important details when retelling stories that were missing key elements, so that the retold story conforms to the story as they expected it to be. Similarly, if a story is told with the events out of order, children often restore it to a more normal order when they retell it.

One way to assess children's understanding of narrative structure is to get them to tell stories themselves. Children's narratives become more coherent with age, and there are age differences in the type of structural framework used to place events within a narrative. Preschoolers tend to tell character or temporally bound narratives, but by 8–10 years of age, children produce more sophisticated event sequences that are causally related and integrated (for a review of children's developing sensitivity to logical structure and knowledge of what makes a good story, see Baker and Stein, 1981).

Knowledge about the information provided by structural elements of stories, such as titles and the beginnings and endings of stories, develops throughout middle childhood. Story comprehension could be impaired by a child's not knowing how to use this information. Titles and introductory information act as context setters, guiding the reader or listener to slot events into structures and schema representations. Additionally, knowledge about the purpose of endings may be important, because endings often summarize the main points of the story and relate the events together.

Some of the storytelling difficulties experienced by young children may be attributable to problems with planning their narratives, perhaps because of memory limitations, rather than a lack of knowledge about narrative structure. When narrative production is supported by a sequence of pictures, many preschoolers are able to construct stories containing episodes that are causally related. It is also probable that some of the developmental gains in knowledge about story conventions and structural coherence are facilitated by literacy experience. Children with several years' experience of reading and listening to stories simply have had more exposure to story conventions and well-formed stories than preschoolers. It is also likely that as children acquire knowledge and use goal plans to interpret everyday events, they become more adept at constructing coherent, integrated representations of such events (whether they be actual or fictional).

Reasons for Comprehension Failure

We now consider the nature and the source of difficulties experienced by children with specific reading comprehension difficulties – i.e., children who have developed age-appropriate word-reading skills but whose reading comprehension skills lag behind. Studies of such children have consistently found that about 8–10% of children in mainstream education can be classified as having such problems (Yuill and Oakhill, 1991), similar to the proportion of children having problems with word reading (Snowling, 2000) (though, of course, the proportion will vary according to the precise definition of what constitutes a sufficient lag in comprehension). There are probably as many sources of reading comprehension difficulties as there are contributory skills. Here we review the evidence that reading comprehension difficulties arise because of deficits in three broad areas: the word level, sentence level, and text level (for a review of this area, see Cain and Oakhill, 2003).

The first view considered is that text comprehension problems arise because of difficulties at the word level. Slow or inaccurate word reading may affect comprehension because it uses up limited processing capacity that is necessary for text comprehension processes such as inference and integration (Perfetti, 1985). However, there is no evidence to date that children who have developed accurate word-reading skills have subtle deficits in their word-reading speed or the automaticity of their word recognition. Similarly, examination of the phonological processing skills of poor comprehenders have not revealed any weaknesses (see, e.g., Cain *et al.*, 2000).

Another word-level skill that may affect text comprehension is vocabulary knowledge. It is one of the best predictors of reading comprehension, and a tempting interpretation of the high correlations is that having a poor vocabulary limits reading comprehension. Some poor readers (those who have both weak word reading and comprehension) have impoverished vocabulary knowledge. However, it is possible to identify children with age-appropriate vocabulary and word-reading skills who experience a severe comprehension deficit. Furthermore, procedures for increasing vocabulary knowledge do not always lead to gains in comprehension level, and simply knowing the meanings of the words in a text does not ensure good comprehension. Thus, a complex relation between vocabulary and comprehension is apparent. One possibility is that reading comprehension and vocabulary may be related indirectly by a third factor, such as the ability to learn from context. A deficit in learning from context may not only impede vocabulary development but also affect the ability to use context to generate inferences and thus lead to comprehension difficulties.

A second view is that comprehension problems arise at the sentence level of processing. Knowledge about syntactic forms is necessary to work out the meanings of sentences in a text, so it is not surprising that early syntactic skills predict later reading ability. There is also evidence that children who start out as good readers might demonstrate reading comprehension difficulties later on, when their word-reading skills enable them to read books that contain increasingly complex sentence structures. However, not all poor comprehenders demonstrate deficits in syntactic knowledge. Clearly, (implicit) knowledge about syntactic forms is necessary to comprehend particular grammatical constructions and, thus, might be expected to be related to comprehension level. Syntactic skills may help children to detect and correct reading errors and, thus, enhance comprehension monitoring (the topic of comprehension monitoring is considered later in this section). However, there are a number of issues of interpretation relating to the research in this area: for instance, the extent to which associations between grammatical awareness and reading are mediated by differences in working memory and decoding, and the direction of the relation between syntactic skills and reading comprehension development (for a further discussion, see Bowey, 1994).

A third view is that poor comprehenders' problems arise because of difficulties beyond the word level and the sentence level, that is, at the discourse level of processing text. Many studies indicate that good and poor comprehenders matched for their word-recognition skills differ in the three components of comprehension related to comprehension development – namely, inference making, metacognition and comprehension monitoring, and understanding text structure. Poor comprehenders generate fewer inferences than good comprehenders, and their difficulties cannot be attributed to differences in general knowledge. Poor comprehenders also are poor at monitoring their understanding of text, demonstrate impoverished knowledge about reading strategies, and exhibit difficulties in the production of coherent and integrated narratives. It is possible that processing deficits limit their ability to execute the skills central to meaning construction. Indeed, poor comprehenders do poorly on measures of working-memory capacity. However, when differences in working-memory capacity are controlled for, skills such as inference making and comprehension monitoring explain comprehension level over and above memory. Thus, a working-memory deficit does not appear to fully explain poor comprehenders' difficulties with the discourse-level skills that enable skilled readers to construct coherent, meaning-based representations of text.

To date, much of the research on poor reading comprehension has used a crosssectional design: good and poor comprehenders, usually matched for chronological age, word-reading ability, and vocabulary knowledge, are compared on the measure of interest. These studies tell us about the things that poor comprehenders have difficulties with, but they do not tell us anything about the *causes* of poor comprehension; they can inform us only about correlations between skill deficits and text comprehension difficulties. For example, children may fail to adequately understand text because they are poor at making inferences. Alternatively, they may be poor at generating inferences because their poor reading comprehension experience has presented few opportunities to develop this skill. Recent investigations have begun to address the issue of causality by using comprehension-age match designs (which are analogous to reading-age match designs), training studies, and longitudinal work, wherein the progress of the children is followed over a number of years (for examples, see Cain and Oakhill, 2003). These research designs enable us to draw some conclusions about the most plausible direction of the relations between component skills and reading comprehension.

Realism and Antirealism

Realism and Antirealism

K Green, Monash University, Melbourne, Australia

© 2006 Elsevier Ltd. All rights reserved.

Realism and antirealism in semantics can take a variety of forms, which are catalogued at the conclusion of this article. First, since realism looks like a metaphysical doctrine, it is necessary to set out how it relates to semantics. Some have claimed that since realism and antirealism concern metaphysics, they have little to do with semantics, truth, meaning, or reference. Michael Devitt and Kim Sterelny argue that realism has two components: it is a doctrine about what exists and a doctrine about the nature of that existence. The realist about commonsense physical objects claims that they exist and that the nature of their existence is to exist independently of the mind. Devitt and Sterelny contrasted this realism with idealism: the view that while ordinary physical objects exist, their nature is to exist 'in the mind' in such a way that their existence is mind dependent (1999: 234–235). These doctrines, Devitt and

Sterelny argued, have nothing to do with semantics, for they can be stated without reference to semantic vocabulary such as 'meaning' or 'truth' (1999: 239). They position themselves as opposed to Michael Dummett, who has argued that the most illuminating way is to see them as implicitly hinging on differences in the theory of meaning (Dummett, 1978, 1991, 1992, 1993).

Realism does have two components, an existence component and one concerning the nature of that existence. Given this, antirealism, with regard to some range of entities, also has two forms. One denies existence. This is the antirealism of the atheist. The other denies mind independence, resulting in idealism and constructivism. In both cases, Dummett's contention, that the debate about what exists can be illuminated by seeing it as concerned with meaning and truth, appears correct. The traditional debate between idealists and realists arose from the skeptical questions posed by René Descartes in his *Meditations*. There Descartes wondered whether we know anything. Since in order to have knowledge one must have true beliefs, we could say that he wondered whether any of his beliefs were true. Descartes assumed that if his beliefs were true, they were made true by a reality that existed independently of him. Yet since he had access to that reality only through his 'ideas,' the question arose as to whether those ideas corresponded to anything, or were, like dreams, mere illusions. The idealists solved Descartes' radical skeptical problem by rejecting the gap between ideas and reality. The existence of the ideas themselves was taken to make our beliefs true. Formulated thus, the traditional distinction between realism and idealism can be seen to hinge on a dispute over what makes our beliefs true. Since it is all one whether we pose the skeptical problem directly for beliefs or think of it in terms of the sentences that express those beliefs, the metaphysical problem lends itself to a semantic formulation (Dummett, 1992: 132–134).

In his early writing, Dummett thought that the way to tackle the issue that divided realists from antirealists was to tackle the notion of truth directly, for he accepted, with Ludwig Wittgenstein, that the sentence is the smallest unit with which one can make a move in the language game and that therefore the notion of truth for sentences was primary (Dummett, 1973: 192–196). Looked at from the point of view of truth for sentences, the realist/antirealist debate hinges on whether truth is independent of us or is simply ideal warranted assertibility. A realist will say that truth is objective and independent of anything we do, but the price to pay for this is that there is no compelling reply to the skeptic. Also, if truth has nothing to do with our holding sentences true, it can play no role in an account of the meaning of those sentences and is in danger of becoming an ungraspable we know not what. If, however, we want an account of truth that is central in a theory of meaning – which is a theory of what we know when we understand sentences – truth should be something we can grasp. Hence, Dummett analyzed truth in terms of warranted assertibility. As a result the principle of bivalence, which says that every meaningful assertoric sentence is either true or false, is given up. For there are sentences that are not justifiably assertible, yet it is not the case that we can confidently say that they are false, that is, that they will never be assertible. When the argument for antirealism directly concerns the notion of truth for sentences, it leads to questioning bivalence and the adoption of intuitionistic logic. But there are other arguments for antirealism that have a different character.

One variety of antirealism points to various speech acts that we can perform other than making truth-assessable statements. It claims that some sentences with which speakers appear to be making statements are not really descriptive utterances. So the possibility of a realist account of the truth of sentences for some area of discourse is excluded, because the discourse is not fact stating. The position of the expressivist in ethics, adopted by A. J. Ayer, is the paradigm of this form of antirealism (Ayer, 1946: 107). Like error theorists, who are discussed later in this article, expressivists suggest that we are in error about the actual semantics of our utterances. For them the realist's error lies in thinking that sentences of the disputed class describe facts.

Yet another issue divides realists about universals from nominalists. Like the realist about the physical world, the realist about universals at first appears to be making a metaphysical claim. It is that universals, as well as particulars, exist independently of us. As with realism about material objects, this claim can be seen to hinge on issues concerning that in virtue of which sentences are true. In order for the sentence 'The rose is red' to be true, one needs more than the mere existence of the particular rose being referred to. One needs it to be the case that the rose is red. If one understands this in terms of the rose instantiating the property of redness, one may be led to postulate the existence of universals, which are what general terms such as 'red' pick out. The nominalist, however, denies that one needs to explain the function of both singular and general terms by assigning a reference to them. According to Quine, for instance, singular terms refer, but predicates express their meanings; it is merely grammatical confusion that leads us to represent predication as a relation between two entities (Quine, 1970: 66–67).

The dispute over the existence of universals shows that not all forms of the realism/antirealism debate directly concern the notion of truth. What is at issue is often a question of the reference, or otherwise, of the subsentential parts of sentences. But these analyses flow naturally from questioning the nature of truth. Aristotle thought that both singular terms and general terms function by referring to, or picking out entities. Singular terms refer to objects; general terms refer to universals. On this model, a simple subject-predicate sentence is a string of names that is true just in case the object referred to by the singular term instantiates the universal referred to by the general term (Aristotle, 1984: 25–27). Bertrand Russell, puzzled by the meaningfulness of singular terms that fail of reference, proposed that in the vast majority of cases we can analyze names and definite descriptions, which appear to refer to objects, as really only involving descriptive phrases and quantifiers. 'The rose on my table is red' is then true just in case there is a unique thing that has the property of being a rose on my table as well as the property of being red (Russell, 1956). Dummett suggested that this is a move in the direction of antirealism (Dummett, 1991: 325). It is a semantic analysis that allows for the reduction of objects to bundles of properties.

Russell's analysis of singular terms can be used to illustrate the way in which antirealism often takes a reductionist form. In 1904 Alexius Meinong proposed that 'The golden mountain is golden' is true in virtue of the subsistence of a nonexistent golden mountain to which the singular term 'the golden mountain' refers. Russell, objecting to a category of nonexistent existents, proposed that we reformulate the true sentence as saying that if anything is a golden mountain, it is golden. Russell was by no means an idealist, but in denying the existence of a referent of 'the golden mountain,' he went against the first component of a realist attitude to golden mountains. Similarly, the physicalist, being an antirealist about thoughts, will have to explain away the apparent truth of sentences such as 'The terrifying thought stopped him in his tracks.' A radical antirealist of the eliminativist slant might deem this sentence literally false. Alternatively, it could be treated as neither true nor false, because it is ill formed. But a reductionist antirealist with regard to thoughts will offer a paraphrase. This might take the form 'Neurons playing the functional role of a warning of danger fired and stopped him in his tracks.' Here the truth of the sentence involving an apparently nonreferring term is accounted for by offering a translation from which it is absent.

Both deeming some sentences neither true nor false because of failures of reference, and offering reductionist paraphrases, constitute forms of antirealism of the broadly error-theoretic type. Error theory received its classic formulation in the work of Mackie (1977). The error theorist usually accepts that there is some range of sentences, typically sentences about physical things, for which the realist semantics holds. But the error theorist argues that we are led into error when we assume that the sentences of some other class share the same semantic structure. Mackie argued this for ethical statements. We are inclined to think of the semantic structure of the sentence 'Charity is good' as analogous to 'Christ is good.' If we accept the Aristotelian semantics sketched earlier in this article, this will involve thinking of charity as a kind of abstract object that instantiates the universal goodness. But these are queer kinds of entity. It is unclear how we have epistemological access to them, and it is arguable that we have been led to postulate their existence by an erroneous extension of the semantics of statements about physical objects. Adopting a version of this approach, Hartry Field argued, against the mathematical Platonist, that statements of mathematics that appear to involve truth grounded in reference to numbers really do no such thing and should not be deemed either true or false (Field, 1980: viii). When a person is persuaded on error-theoretic grounds that a realist semantics for some class of sentences is mistaken, but nevertheless wants to save the appearance of truth and falsehood for sentences of this class, he or she is characteristically forced to offer a reductionist account.

We can now construct a brief catalogue of forms of realism and antirealism. Global realism would treat all sentences realistically, and an ultra-global realist would accept not just classical logic but also the Aristotelian semantics according to which all singular terms refer to objects, while general terms refer to universals. Almost no philosopher is a global realist, and global antirealism is equally rare. Disputes arise in many areas. Platonists in mathematics oppose error theorists and constructivists; realists about mental entities oppose eliminativists and various forms of reductionist; realists about theoretical entities oppose instrumentalists; realists about commonsense material objects oppose phenomenalists and idealists; realists about possible worlds oppose ersatz theorists; realists in ethics oppose subjectivists, expressivists, and error theorists; realists about the past oppose presentists; and realists about the future oppose antirealists, for whom the future does not exist. Reductionist antirealism cannot be global, since it always involves a class of sentences interpreted realistically that provides a reduction class. Yet not all antirealism is reductionist. In the case of antirealism about the

future, there is a direct intuition that future-tense sentences are not now either true or false. Antirealists may deem some class of sentences to be nondescriptive, or descriptive but not involving a realist notion of truth. Among those who accept realist truth, there are those who analyze truth in terms of the existence of objects and universals, and others who take an antirealist attitude toward either objects or universals.

Reconstruction, Cultural

J T Katz, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the main tasks of historical and comparative linguistics is reconstruction – the recreation, to the best of our abilities, of a linguistic situation at some point in the past. Using broad knowledge of tendencies in language change and employing above all the justly famous and powerful technique known as the Comparative Method (the classic account remains Meillet, 1925), scholars are able to explain with some precision the closely linked matters of linguistic evolution and relationship, specifically how a given language has evolved from its linear predecessor and how the language in question is related to other tongues that are not part of the same line but whose own histories show that they once intersected with it. Most work concentrates on phonology and morphology since sounds and smaller combinations of sounds are in a certain obvious sense the easiest units of language to deal with; the reconstruction of syntax is, however, playing an increasingly large role in linguistic research.

But it is important not to forget semantics and pragmatics: since speech exists in the first place for communication, coming to terms with the meaning of the reconstructed morphemes and words is an evident desideratum. While this may sound straightforward, interpreting the lexical evidence that emerges from historical and comparative linguists' occupation with formal matters of phonology and morphology is often not at all easy: semantic change is very much a matter of (human) tendencies rather than (scientific) rules (see, e.g., Fortson, 2003), relying on cultural situations and norms that may be hard for outsiders to fathom, especially outsiders who are looking back on a bygone civilization. It is true that even some phonological changes can seem non-evident unless taken apart and examined very closely, but in historical semantics, the 'surprise factor' is always there. Without an understanding of culture-specific religious and legal rituals, for example, it is not possible to explain why there should be a morpho-phonological relationship between the English words *blood* and *bless* (the verb originally meant 'consecrate with blood') or exactly how the Latin word *testis* (← **trit(j)o-sth$_2$-o-*, literally 'standing as third') could have come to mean in the first place 'witness' and then also 'testicle' (see Katz, 1998).

Whatever one may think of the Sapir-Whorf hypothesis, there is clearly some sort of relationship between worldview and linguistic expression, and the goal of cultural reconstruction (sometimes known as

future, there is a direct intuition that future-tense sentences are not now either true or false. Antirealists may deem some class of sentences to be nondescriptive, or descriptive but not involving a realist notion of truth. Among those who accept realist truth, there are those who analyze truth in terms of the existence of objects and universals, and others who take an antirealist attitude toward either objects or universals.

Reconstruction, Cultural

J T Katz, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the main tasks of historical and comparative linguistics is reconstruction – the recreation, to the best of our abilities, of a linguistic situation at some point in the past. Using broad knowledge of tendencies in language change and employing above all the justly famous and powerful technique known as the Comparative Method (the classic account remains Meillet, 1925), scholars are able to explain with some precision the closely linked matters of linguistic evolution and relationship, specifically how a given language has evolved from its linear predecessor and how the language in question is related to other tongues that are not part of the same line but whose own histories show that they once intersected with it. Most work concentrates on phonology and morphology since sounds and smaller combinations of sounds are in a certain obvious sense the easiest units of language to deal with; the reconstruction of syntax is, however, playing an increasingly large role in linguistic research.

But it is important not to forget semantics and pragmatics: since speech exists in the first place for communication, coming to terms with the meaning of the reconstructed morphemes and words is an evident desideratum. While this may sound straightforward, interpreting the lexical evidence that emerges from historical and comparative linguists' occupation with formal matters of phonology and morphology is often not at all easy: semantic change is very much a matter of (human) tendencies rather than (scientific) rules (see, e.g., Fortson, 2003), relying on cultural situations and norms that may be hard for outsiders to fathom, especially outsiders who are looking back on a bygone civilization. It is true that even some phonological changes can seem non-evident unless taken apart and examined very closely, but in historical semantics, the 'surprise factor' is always there. Without an understanding of culture-specific religious and legal rituals, for example, it is not possible to explain why there should be a morpho-phonological relationship between the English words *blood* and *bless* (the verb originally meant 'consecrate with blood') or exactly how the Latin word *testis* (← **trit(j)o-sth$_2$-o-*, literally 'standing as third') could have come to mean in the first place 'witness' and then also 'testicle' (see Katz, 1998).

Whatever one may think of the Sapir-Whorf hypothesis, there is clearly some sort of relationship between worldview and linguistic expression, and the goal of cultural reconstruction (sometimes known as

linguistic paleontology) is to use language and etymology to gain access to the way people talked about their environment. Forms in related languages may lead scholars to reconstruct proto-words for 'fish' and 'loom', but it requires more than a reckoning of sounds and morphemes to determine with any degree of plausibility just what species of fish speakers were referring to or exactly what kind of instrument they actually used for weaving. There is of course an important difference between fish and looms, namely that the one is natural, the other man-made. When scholars speak of cultural reconstruction, they frequently mean to encompass both. Perhaps largely because of the inordinately great role that the evidence of words for kinds of fish and trees – especially the salmon (Diebold, 1985 gives a salutary account) and the beech (see, e.g., Friedrich, 1970: 106–115) – has played in scholars' highly controversial attempts to specify the homeland ('Urheimat') and early migrations of the Indo-Europeans (see, e.g., Mallory, 1989), the reconstructed vocabulary of the natural world has historically figured more prominently than words for items of material and intellectual culture. My emphasis in what follows is on the latter, as well as (in part on account of my own limited competence) on Indo-European peoples. (Most textbooks on historical and comparative linguistics rely heavily on Indo-European evidence, but two good ones that do not and that do discuss cultural reconstruction are Crowley, 1997, whose examples come mostly from Australia and the Pacific, and Campbell, 2004, who stresses the languages of the Americas.)

In the earliest days of scientific linguistics, the relationship between proto-language and proto-culture was taken for granted (Jacob Grimm, for example, was interested as much in what it meant to *be* German as in what it meant to *speak* it), but the rise of Neogrammarianism in the late 19th century led to a heavy emphasis – still not overcome – on formal methodology and the view that the concomitant investigation of cultural questions (the so-called 'Wörter und Sachen'-approach, championed most of all at that time by Otto Schrader: see especially Schrader, 1907 and 1917–1929) was at best the poor stepsister. (It is telling that there is no chapter on cultural reconstruction in the latest compendium of research on historical linguistics, Joseph and Janda, 2003.) The situation is slowly changing, though the adherence of certain scholars to repugnant ideological (racist or nationalistic) interpretations of linguistic data has not helped raise the status of reconstructive work in academia (see, e.g., Lincoln, 1999). As for the relative status of linguistic techniques vis-à-vis others in the reconstruction of prehistory (Day, 2001 provides a fine synthesis), it remains to be seen what will come of the widely publicized and aggressive battles between linguists and archaeologists (Blench and Spriggs, 1997–1999 is a very useful collection, especially in this context volume 2 [1998], subtitled *Correlating archaeological and linguistic hypotheses*) and now also geneticists and evolutionary biologists (see, e.g., Gray and Atkinson, 2003, whose time-scale nearly all linguists consider impossible).

Cultural reconstruction is above all part of the history of ideas, a way into the metaphors people live and lived by: that we *surf the web*, for example, and that the Navajo call corn *naadą́ą́'*, literally 'enemy-food', because they learned of it from the Pueblo and that early Indo-Europeans personified evening as 'the shrouded one' because in their mythology, the sky got dressed at the end of the day (see Janda, 2000: 200–211 and Katz, 2000). Coming to grips with the nuances of words is often essential for determining the pragmatic fulcrum of semantic change and, more generally, provides a good window onto a culture's organization and values: what it does with the natural materials found in the environment; how it functions sociopolitically and economically at both the micro (family) and the macro level (society as a whole); what its legal and religious systems are; and how it expresses itself artistically. (The most remarkable works that cover all these topics are Benveniste, 1969 and the papers collected in Watkins, 1994: volume 2; see also Buck, 1949, Gamkrelidze and Ivanov, 1984: volume 2, and Mallory and Adams, 1997 [plus Zimmer, 1999], as well as the good summary accounts in Watkins, 2000: vii–xxxv and *passim* and Fortson, 2004: 16–47.) Let us briefly consider each of these areas in turn.

It is largely uncontroversial that the Proto-Indo-Europeans were an agricultural people who plowed (*h_2erh_3-: Latin *arāre*, whence English *arable*) their fields (*$h_2e\hat{g}$-*ro*-: Latin *ager*, as well as English *acre*; a derivative of the root *$h_2e\hat{g}$- 'drive'), cultivated grains (probably at least wheat or barley, though precise linguistic reconstructions are difficult), bred cattle (*g^w*ow*-: Latin *bōs* and English *cow*) and other livestock (*$pe\hat{k}u$-: Latin *pecū* and, interestingly, English *fee* [< Old English *feoh*, in effect 'valuable four-legged property']), made ample use of dairy products (a variety of words can be reconstructed more or less precisely, including the predecessor(s) of Latin *lac* and English *milk*), and spun (*(s)*neh*$_1$-: Latin *nēre*; cf. also English *needle*) wool (*$h_{2/3}w\underset{\circ}{l}h_1$-*neh*$_2$-). Questions about the use of native animals, vegetables, and minerals that generate somewhat more excitement concern two related matters: the domestication of the horse and the invention of the wheel and evolution of the chariot. The distribution of the preform *k^we-$k^wl(h_1)$-*o*-across the Indo-European languages

(e.g., English *wheel* and Tocharian B *kokale* 'chariot'), coupled with some archaic features that appear to be part of the paradigm's accentual pattern, makes it virtually certain on linguistic grounds that the Proto-Indo-Europeans had at least this one word for 'wheel', a derivative of the root *$k^w el(h_1)$- 'turn' (a second widespread word is based on the root *ret-'run'). This is interesting for a number of reasons, not least because the description of the Proto-Indo-Europeans' world sketched in the first sentence of this paragraph suggests a late Neolithic society of the 4th millennium B.C., which is precisely when we find the first archaeological evidence for wheels (ca. 3300 B.C.), an invention that would, not very surprisingly, have been referred to in the first instance with a wholly transparent neologism (see Fortson, 2004: 38). The place and date of the domestication (*$demh_2$-: Latin *domāre* and English *tame*) of the horse (*$h_1e\hat{k}wo$-: Latin *equus*, whence English *equine*) is more controversial still, and it must suffice here to state that there is possible evidence for tamed horses in Eurasia around 3500 B.C.

Indo-European society was certainly patriarchal and patrilineal (its kinship system is generally thought to have originally been more or less of the Omaha type, but see Hettrich, 1985 for an interesting dissent); accordingly, we know more about men's exploits than women's, though E J W Barber (see, e.g., Barber, 1991) has deftly reconstructed the linguistic and material world of 'women's work', the production of textiles. The self-designation of the Proto-Indo-Europeans is unfortunately not wholly clear and neither are the oldest words for 'clan', though it is good to remember that civilizations the world over frequently call themselves simply 'The People' (e.g., Navajo *Diné*), which is roughly the meaning of the reasonably widespread preform *$teuteh_2$- of, for example, *Dutch* and *Deutsch* (the German word for 'German'). The leader of the tribe was the *$h_3rē\hat{g}$- 'king' (built to the root *$h_3re\hat{g}$- 'straighten; rule'), a word preserved in Latin *rēx* and found in such Germanic names as *Richard* (< Old High German *Rīco-hard* 'strong in rule'), not to mention *Theodoric* and *Dietrich*, which, indeed, both go back precisely to a compound of *$teuteh_2$- plus *$h_3rē\hat{g}$-, 'people's king'. An issue that has exercised scholars for the past couple of generations is the utility of Georges Dumézil's 'trifunctionalism' as a model of Proto-Indo-European society. According to Dumézil (see, e.g., Dumézil, 1958), free males belonged to one of three classes: kings and priests (first function), warriors (second), and farmers and other commoners (third). The linguistic and philological evidence for this – and for its wider application to divinities – remains disputed.

Because legal and religious texts tend cross-culturally to be repositories of linguistic archaism, it is *a priori* likely that investigating the language of a number of such documents will tell us a great deal about the proto-culture in question. The vocabulary of Indo-European law ('that which is laid down' < *legh- 'lie, lay', a root that some believe also lies behind Latin *lēx*) has not yet received as much attention as it deserves, but it seems likely that the principal words for 'law' were *jows (cf. Lat. *iūs* and the compound *iū-dex* 'judge', literally 'law-pronouncer') and one or more derivatives of the root *d^heh_1- 'put', as in Classical Greek *$t^hémis$*, Vedic Sanskrit *dhā́ma-*, and English *deed* and *doom* (which originally meant 'judgment', witness *doomsday*). It is noteworthy (see Watkins, 1995: 434, with n. 5) that the very first attested Indo-European word that has come down to us is a 19th-century B.C. borrowing into Old Assyrian of (pre-)Hittite *išḫiul* 'contract' (a derivative of the verb for 'bind'). Recent work on Greek and Indic marriage by Stephanie W Jamison (see, e.g., Jamison, 1999) has added considerably to our understanding of Indo-European legal rights and responsibilities, including – remarkably – those of women. As for religion (Latin *religiō* is probably etymologically 'that which binds (-*lig*-)', a derivative of *$lei\hat{g}$-), the Proto-Indo-Europeans were polytheistic, with the head, or 'father' (*ph_2ter-), of the gods – addressed in the vocative as Vedic Sanskrit *dyàuṣ pítar*, Greek *Zeû páter*, and Latin *Iū-piter* (i.e., Jupiter) – the deification of the bright sky, *djew-. It is worth noting that the Latin word *deus* (as in '*dei*-fication') is a derivative of this same root, whereas Greek *$t^heós$* (as in 'poly-*the*-istic'), like also Latin *fēstus* (whence our word *festival*), goes back to *d^heh_1s-, which may well be an extension of the root for 'put' noted above. The English word *god*, incidentally, probably derives from *$\hat{g}^hew$- 'pour' and refers to the spirit immanent in a tumulus, perhaps a *kurgan*, the Eurasian burial mound that some archeologists, notably Marija Gimbutas, associate with the Proto-Indo-Europeans (see Watkins, 2000: 31, resuming an argument made in 1974; Kupfer, 2004 presents a different and to my mind less convincing picture of the details). Our knowledge of Proto-Indo-European religious culture has recently been greatly expanded in two surpassingly brilliant books by Michael Janda (Janda, 2000, 2005).

Finally, there is verbal art, a cover term that subsumes a range of genres in which stunning archaisms and delightful new turns of phrase are woven together in a special way. In Proto-Indo-European society, the poet (for whom there is no single reconstructible designation) was one of the most highly regarded figures, and thanks to two profoundly influential

works, Schmitt, 1967 and Watkins, 1995, and the further research they have inspired (e.g., Matasović, 1996), the nuances of what is usually called 'Dichtersprache' are becoming ever more apparent. It is clear that at least some metrical and strophic forms found in the individual daughter languages go back to Proto-Indo-European times and that certain artful techniques were part of the repertoire of bards who told tales, which then became the myths of the separate Indo-European peoples (see, e.g., Puhvel, 1987) – of the beginning of the world and of glory in battle and of fights against monsters. For comments on the advances in and pitfalls of attempting to reconstruct the details of the genre of epic in Proto-Indo-European, see Katz, 2005; the inherited tradition of riddles is the subject of Katz, forthcoming.

Cultural reconstruction in effect puts history back into historical linguistics, and this is a difficult business, for it involves expanding formal linguistic methods into the larger and messier world of realia, of real life as it is and was once lived. Still, once we acknowledge the simple truth that real human beings spoke the languages that we are doing our best to reconstruct, it becomes part of our job as linguists to take account of, and reconstruct as best as we can, the circumstances in which these languages were used and under which they developed.

Reconstruction, Morphological

B Fortson, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The reconstruction of the morphology of a protolanguage is beset with certain difficulties that do not attend the reconstruction of phonology. Peeling back the layers of historical change and undoing them – the essence of reconstruction – is in principle easy when the changes are regular and exceptionless, as is the case with sound change (at least under the Neogrammarian model). Morphological change, as is well known, is quite a different kettle of fish; however, the usual characterization of it as entirely irregular is perhaps too strong, and depends on where one seeks to localize a given change and how one defines 'morphological change' in the first place.

Certain changes called morphological change are in fact lexical changes, that is, they result in a change to individual items in the lexicon and do not affect the morphological system of the language. (Even a lexical change that removes from the language the last remaining example of a once-productive morphological process has merely erased all evidence that such a process once existed; since the process was no longer productive anyway, the morphological system was unaffected by the word's disappearance. An example of such a case is the dialectal English generalization of *was* throughout the preterite paradigm of the verb *be* that removed the last example of the once-common distinction between the singular and plural in the preterite.) The 'morphological system' will be, for convenience, here defined as the sum total of elements and rules needed for derivation and inflection. Examples of changes that are often called morphological changes but whose effects are typically lexical in scope include analogy, paradigm leveling and split, folk etymology, false segmentation (of the type [*a*] *nadder* > [*an*] *adder*), double-marking, back-formation, contamination, and taboo deformation. As lexical changes, they are by definition unpredictable and irregular, and their effects can greatly obscure morphological history (as well as phonological history).

When the effects of these changes cause a learner to reanalyze part of the data as reflecting a morpheme or rule that was not present in the source grammar, then the learner's morphology will come to be different from the morphology of the source grammar and true morphological change will have occurred. A true morphological change, involving (for example) a new morphological rule, is in fact 'regular' in that it affects in the same way all the members of whatever class or category it applies to. (The class may be small and limited in number, or it may be open, as is the case with the nouns to which the *s*-plural rule applies in English.)

Once a new productive rule enters the language, it will usually erase traces of earlier rules that applied to the same forms. But it is to be expected that the morphology of the most frequent lexemes in a language will have the least opportunity of being overlooked by a learner, and that these items will stand the best chance of surviving in the face of morphological change. For this reason, irregular forms – those that are not generable by the productive morphological rules of a language – are highly represented among a language's most frequent items. These exceptions are therefore a valuable source of information about

Reconstruction, Morphological

Introduction

The reconstruction of the morphology of a protolanguage is beset with certain difficulties that do not attend the reconstruction of phonology. Peeling back the layers of historical change and undoing them – the essence of reconstruction – is in principle easy when the changes are regular and exceptionless, as is the case with sound change (at least under the Neogrammarian model). Morphological change, as is well known, is quite a different kettle of fish; however, the usual characterization of it as entirely irregular is perhaps too strong, and depends on where one seeks to localize a given change and how one defines 'morphological change' in the first place.

Certain changes called morphological change are in fact lexical changes, that is, they result in a change to individual items in the lexicon and do not affect the morphological system of the language. (Even a lexical change that removes from the language the last remaining example of a once-productive morphological process has merely erased all evidence that such a process once existed; since the process was no longer productive anyway, the morphological system was unaffected by the word's disappearance. An example of such a case is the dialectal English generalization of *was* throughout the preterite paradigm of the verb *be* that removed the last example of the once-common distinction between the singular and plural in the preterite.) The 'morphological system' will be, for convenience, here defined as the sum total of elements and rules needed for derivation and inflection. Examples of changes that are often called morphological changes but whose effects are typically lexical in scope include analogy, paradigm leveling and split, folk etymology, false segmentation (of the type [*a*] *nadder* > [*an*] *adder*), double-marking, back-formation, contamination, and taboo deformation. As lexical changes, they are by definition unpredictable and irregular, and their effects can greatly obscure morphological history (as well as phonological history).

When the effects of these changes cause a learner to reanalyze part of the data as reflecting a morpheme or rule that was not present in the source grammar, then the learner's morphology will come to be different from the morphology of the source grammar and true morphological change will have occurred. A true morphological change, involving (for example) a new morphological rule, is in fact 'regular' in that it affects in the same way all the members of whatever class or category it applies to. (The class may be small and limited in number, or it may be open, as is the case with the nouns to which the *s*-plural rule applies in English.)

Once a new productive rule enters the language, it will usually erase traces of earlier rules that applied to the same forms. But it is to be expected that the morphology of the most frequent lexemes in a language will have the least opportunity of being overlooked by a learner, and that these items will stand the best chance of surviving in the face of morphological change. For this reason, irregular forms – those that are not generable by the productive morphological rules of a language – are highly represented among a language's most frequent items. These exceptions are therefore a valuable source of information about

earlier morphological rules in a language, and gave rise to the oft-repeated maxim that morphological reconstruction proceeds on the basis of exceptions.

Following this maxim does not immunize the reconstructivist from pitfalls, however, and it is to these that we now turn.

Reconstructing on the Basis of Exceptions

Synchronic innovatory morphological processes with diachronic implications include primarily analogy, an imprecise (and sometimes over-invoked) term that will be used here for convenience to cover any extension of a morphological process to a lexeme to which it previously did not apply. Forms are innovated daily in this way; some of them get picked up by other speakers, make it into the historical record, or both.

Since analogy involves the extension of synchronically productive morphological processes, any and all forms produced by productive processes can be suspected of being historically recent creations, generated on the fly by individual speakers. ('Productive' is used here in its broadest sense, to describe any process that can be analogically extended.) If two related languages have a particular productive process in common (say, the *-s* plural of English and German), the presence of cognate or identical forms exhibiting that process (e.g., English pl. *sofas*, German *Sofas*) in no way guarantees that the languages' ancestor had those forms too (we would not want to reconstruct a Common West Germanic paradigm **sofa, *sofas*). It is only when cognate forms are found exhibiting the same synchronically **unproductive** process that cognacy of both the process and the forms can be entertained. Thus, the equation of *is/were* with German *ist/waren*, evincing identical and unpredictable suppletion, strongly suggests common inheritance of the two paradigms.

Even here, though, one can be led astray by parallel independent developments. The equation of English *mouse/mice* with German *Maus/Mäuse* is good prima facie evidence for a Common West Germanic word for 'mouse' that formed its plural by umlauting, except that we know on independent grounds that umlaut happened well after the breakup of Common West Germanic, and additionally spread to German only some time after it had run its course in English. Without such knowledge, however, the comparative method would dictate the reconstruction of an umlauting paradigm for proto-West Germanic, since in both English and German, umlaut is not a regular and predictable process of forming plurals.

Similarly, one of the ways of forming a perfect in Latin involved changing a root vowel *a* or *ā* to *ē* or *e*, as in the 1st person singular perfects *ēgī cēpī fēcī stetī dedī* from (infin.) *age-re cap-ere fac-ere stā-re da-re*. Latin's relative Oscan had this process too, as exhibited by *hipid* (historically **hēbēt*), the 3rd person singular perfect subjunctive of the verb corresponding to Latin *habeō* 'have.' A perfect **hebuī* or **hēbī*, not attested for Classical Latin, was analogically created at some point in the pre-Romance period, because certain forms of the Italian simple past (1st sing. *hebbi*, 3rd sing. *hebbe*, 3rd pl. *hebbero*) continue a perfect stem with an *ĕ*. If all we had at our disposal was Oscan *hipid* and Italian *hebbi, hebbe* (plus a knowledge of the sound changes), we would probably be tempted to reconstruct **hĕb-* as this verb's perfect in the common ancestor of Italian and Oscan, namely Proto-Italic. (Students of these languages will know that the data are being fudged a bit here for illustrative purposes; the long-vowel perfects like *ēgī* are historically quite different from the short-vowel perfects like *stetī*.) Conservatively, we are licensed to project only the *a/e* pattern onto Proto-Italic, rather than (without external evidence) the exhibition of that pattern by a particular lexeme. And the pattern itself can only be projected onto the protolanguage if it cannot be shown to be independently innovated in its daughters.

When cognates are compared across several languages and some of the cognates are morphologically peculiar in their traditions and others are not, if the morphological peculiarities are comparable, then the simplest hypothesis is that they are inherited and the other languages have regularized the peculiarities. A well-known example of this concerns the reconstruction of the Proto–Indo–European word for 'daughter-in-law,' a feminine noun that has the expected feminine paradigm in **-ā-* in some languages (e.g., Sanskrit *snuṣā́*, Old English *snoru*, Old Church Slavonic *snŭkha*) but an unexpected *o*-stem paradigm in others (*o*-stems are usually masculine or neuter; e.g., Greek *nuós*, Latin *nurus*, Armenian *now* [genit. *nowoy*]). Since there is no reason for speakers to have remodeled an inherited *ā*-stem feminine as an exceptional *o*-stem feminine, the *o*-stem forms are surely inherited, and the *ā*-stem forms independent regularizations.

Less clear-cut, of course, are cases where determining what is regular and what is irregular is a whole task unto itself. Perfects of the Latin 3rd conjugation were built with a multitude of different formations, essentially all of which underwent some analogical spread at one time or another. The class was closed – practically no new verbs during the Classical period entered the 3rd conjugation – meaning there is little evidence for which, if any, of these formations was a default for the class. Comparisons between 3rd-conjugation perfects and cognate forms in other

Indo-European languages must therefore be made carefully, with as detailed an understanding as possible of the histories of the different classes.

The dictum to reconstruct on the basis of exceptions also invites caution for another reason, namely that exceptional forms themselves are not necessarily more archaic, and can lead the linguist astray in the absence of more detailed data. The history of the perfect plural stem in Sanskrit is a good case in point. Perfects of roots of the shape *CaC* were formed in Sanskrit by reduplicating the root-initial consonant; thus to *par* 'fill' was formed *pa-par-*, the singular perfect stem. The dual and plural perfect stem was formed in the same way but with absence of the root vowel, hence *pa-pr-*, with an internal consonant cluster. As a result of sound changes, the prehistoric dual/plural perfect stems **sa-sd-* (root *sad* 'sit'), **ya-ym-* (root *yam* 'extend'), and **ya-yt-* (root *yat* 'stretch') became *sed-, yem-, yet-*. The resulting pattern singular *sasad-:* plural *sed-*, *yayam-: yem-*, *yayat-: yet-* was gradually extended to other roots.

A linguist looking at this stage of Sanskrit (a bit anterior to the earliest attested stage), simply going by the raw numbers where perfect plural stems of the type *papr-* outnumbered those of the type *sed-*, might decide that the *sed-* forms, being exceptional, were older. In this case, though, they are the rising upstarts. A look at a later stage would reveal a different situation. By the time of the Rigveda (the earliest Sanskrit text), ten *CaC*-roots that originally formed their perfects with reduplication in the plural stem have taken over the *sed-* pattern (e.g., *pec-* to the root *pac* 'cook'), in most cases completely ousting reduplication, and an equal number preserve reduplication; by the later Classical stage, the number of roots preserving reduplication had been reduced to five (Whitney, 1889: 284–285). The linguist looking at late prehistoric Sanskrit would obviously need to consider other factors than raw numbers in order to come to the correct conclusion.

Morphotactic Comparison

Cognate languages sometimes agree in having identical rules for the concatenation of derivational or inflectional morphemes (morphotactic rules), but without cognacy of the actual morphemes (as in Siouan languages). In such instances, some linguists have been tempted to apply the comparative method to the morphological templates (the sequences of fixed positions taken by the morphemes), and claim that the templates are inherited even if there has been innovation in the morphemes themselves. (An analogy in the lexical domain would be to claim that a protoparadigm was suppletive for a particular word if the daughter languages show suppletion in that word but with different suppletive forms, such as Russian *let* 'years' [genit. pl.], *god* [sing.] compared to Polish *lata* [pl.], *rok* [sing.].)

How valid the results of such comparison are is a somewhat vexed question. Under traditional understanding, morphological reconstruction cannot operate without cognate morphemes to compare; and certainly if the goal is to reconstruct the morphological inventory of a parent language, comparison of morphotactics alone is bootless. Additionally, since inflectional morphemes are positioned by syntactic rules, what is really being compared in this scenario is the syntactic systems of two cognate languages. In either case, little information about the morphology of the protolanguage can be gleaned.

Similar situations occur outside the realm of concatenative rules, as when two cognate languages share the same case-system but different case-endings. The two Tocharian languages have, between them, seven innovated nominal cases, the endings of three of which (comitative, allative, and ablative) are not cognate. Does one then reconstruct for Proto-Tocharian the existence of those three desinential categories for Proto-Tocharian in the absence of cognacy of the morphemes themselves? Clearly the answer is no, since if one posits this system, the development from it to the attested Tocharian languages would entail the loss and replacement of all three original endings (either all of them in one language, or some of them in one language and the rest in the other). More likely, Proto-Tocharian had a collection of postpositions, some of which underwent independent but parallel grammaticalization in its two daughters.

Convergent evolution must not be overlooked as a source of morphological similarity. The two unrelated Caucasian languages Georgian and Udi (the former is Kartvelian, the latter Lezgian [Northeast Caucasian]) have the same preverb–plus–verb template, in which an agreement marker intervenes between preverb and verb, but the two systems have entirely different sources within their respective families (Harris, 2003). From within a single family, the Slavic languages have a category of animacy in nominal paradigms, whereby accusatives of animate nouns have the same endings as the genitive, rather then the 'regular' accusative (of inanimates). Each Slavic language today has a different system. In Russian, all noun classes participate in it; in Novi Serbo-Croatian, only *o*-stems do. In Old Church Slavonic, which was fairly close to reconstructed Common Slavic, this morphosemantic feature was extremely limited – to the accusative singular in *o*-stems. The system has therefore expanded in each Slavic language independently and partly along parallel lines; if Old Church Slavonic were

not attested, we would likely reconstruct too much of it for Common Slavic (S. Thomason, personal communication).

Internal Morphological Reconstruction Based on Allomorphy

The synchronic establishment of underlying morphemes on the basis of allomorphic alternations is essentially the same thing as the internal reconstruction of a language's morphological history. To take a simple example, Latin has various present active infinitive formations, exemplified by *amāre* 'to love,' *movēre* 'to move,' *capere* 'to take,' *audīre* 'to hear,' *esse* 'to be,' *velle* 'to want,' *ferre* 'to carry.' We can isolate a suffix *-re* in the first four forms, but the last three forms exhibit a doubling of a consonant followed by *-e*. Examination of other forms in the paradigms of these three verbs reveals the verb stems to be *es-*, *vel-*, and *fer-*, indicating that the infinitive suffix began with a consonant that assimilated to the preceding consonant. Other evidence from the language reveals that the consonant for all these forms was once *s*, which was rhotacized to *r* between vowels (hence *amāre*, *movēre*, etc.); remained following another *s* (*es-se*); and assimilated to a preceding liquid (whence *vel-le, fer-re*). From this evidence, we can reconstruct **-se* as the pre-Latin present infinitive active suffix. (Additional evidence would allow us to refine the reconstruction to **-si*.)

Some forms of allomorphy are not so simple, and involve what has often been called a subtraction morpheme. In French, for example, there is no way to predict that the feminine of /mi/ 'sent' (passive participle) requires the addition of /-z/ while the feminine of /fri/ 'fried' requires /-t/, and the feminine of /ʃo/ 'cold' requires /-d/. One can analyze this alternation with the following rule: derive the masculine from the feminine by deleting the final consonant of the feminine. But many linguists doubt that such rules actually exist; they have proposed an alternate rule for the French data, namely, posit the final consonant as underlyingly present in the masculine forms, and then posit a morphophonological rule that deletes the final consonant. This does not involve actual subtraction of an element from one category to form another category, but allows both forms to be independently derived from a single underlying form. However, under either of these scenarios, there is a serious problem: a French speaker would be unable to form the feminine of an adjective to which he or she only knew the masculine. Various varieties of French, in fact, have reanalyzed one of the possible consonants coming at the end of feminines as a default feminine marker (for example, [-z] in the case of Northern French). Speakers thus, clearly analyzed the feminines as derived from the masculines and, from the pool of distinctive differences between the two, latched onto one as the default.

Cases like this are quite common, and they typically come about in the same way: sound changes eliminate the final sound or syllable from one set of forms but not from another set where it was protected by additional derivational or inflectional material. The history behind the French facts is well known: what synchronically appears as a derivational suffix (in this case, /-z/, /-t/, or /-d/) is in reality the old stem-final consonant. At an earlier stage, the masculines were /miz/, /ʃod/, and /frit/, while the feminines were /mizə/, /ʃodə/, and /fritə/; /-ə/ was the feminine suffix. In time, deletion of word-final stops produced the masculines /mi/, /ʃo/, and /fri/, and subsequently word-final schwa deletion produced the feminines /miz/, /ʃod/, and /frit/. For a more detailed discussion of the process with other examples, see the important study by Hale (1973).

The synchronic French data allow one to reconstruct the whole history except for the phonetic shape of the original feminine suffix (all that can be said for sure, based on the evidence presented above, is that there was one that was added to the stem-final consonant). A more difficult situation exists in Hawaiian, where the verb form known as the passive is formed with the suffix [-ʔia] in almost all verbs, with a small handful of exceptions where the consonant is something other than a glottal stop. Faced with these facts, a lucky soul might hit upon the idea that *-ia* (which is what the variant suffixes have in common) was the original suffix, and the consonant preceding it was an old stem-final consonant that had been deleted in other forms where it would have been word-final; but other analyses are also possible without additional evidence (such as [-ʔia] is innovatory and one of the exceptional variants was the original suffix). The truth is that [-ʔia] was generalized in the same way that [-z] was generalized as a feminine marker in Northern French (only [-ʔia] has spread much, much more widely than [-z].

Syncretism

All reconstruction is limited by the available evidence. Syncretism, the collapse of inflectional systems (such as case-systems) due usually to a combination of phonological and analogical factors, can obliterate evidence of original inflections. The modern Romance languages, for example, have lost all the Latin case distinctions in nouns, and the few fossilized remnants would not suffice to recreate any full Latin paradigm (e.g., from French, the place-name

Aix that continues the Latin locative plural *Aquīs* 'at the waters'; the pronoun *rien* 'nothing' < Latin accusative singular *rem* 'thing'; *encore* 'again' dimly preserving the ablative singular ending *-ā* in *(*)hinc hā (h)ōrā*, where the *-o-* continues **-au-* < *-ao-* < **-ā ō-* [*ō* alone would have come out *eu*, as in *heure* < *hōrā*]; and the noun *chandeleur* 'Candlemas' < Latin genitive plural **candēlōrum*).

The preservation of relic forms through semantic specialization (essentially the process known as Kuryłowicz's Fourth Law of Analogy), leading to their being learned as separate lexical items not part of the paradigms of the words that they were originally inflections of, is necessary for any kind of internal reconstruction of inflectional changes such as gain or loss of case-endings, paradigm leveling, and paradigm split. In Latin, a *v* (also written *u*) was lost between a consonant and *u*, leading to allomorphy in some nominal and adjectival paradigms; but this *v/u* was restored, so that what should have been, e.g., nominative singular *ecus* 'horse,' genitive *equī*, was restored to *equus equī*, and what should have been *parus* 'small,' genitive *parvī* was restored to *parvus parvī*. The restoration erased the effects of the sound change, but luckily for scholars, forms like *parum* 'too little,' originally the accusative singular (from *parvum*) which was specialized as an adverb, remained because, due to their separation from their original paradigm, they escaped the restoration of the *-v-* and provide evidence for the leveling that must have taken place elsewhere.

The above survey has touched on some of the problems that attend morphological reconstruction. Readers interested in a listing of the different available procedures should consult the carefully laid-out material in Koch (1996).

Syntactic reconstruction has not figured prominently in historical linguistic investigations, as can be surmised from the fact that the index of the recent 881-page *Handbook of historical linguistics* (Joseph and Janda, 2003) lists just seven pages, all in the same article, where it is discussed. As Fox observes, "Syntactic reconstruction is a controversial area … scholars working within the framework of the classical Comparative Method have been far less successful in applying their methods here than in the case of phonology or even morphology" (1995: 104; see also Jeffers, 1976). And in discussing this topic elsewhere, Fox does not point to any methods other than the Comparative Method that have offered promising results (1995: 104–109, 190–194, 250–253, 261–270).

Efforts to reconstruct syntax can be traced at least as far back as 1893–1900, when Delbrück (as cited in Lehmann, 1992: 32) reconstructed OV word order for Proto-Indo-European. By far the most ambitious early effort at reconstructing syntax is Schleicher's 'Proto-Indo-European fable', which was considered a rash enterprise even in those pre-Neogrammarian times (1868; as cited and translated in Jeffers and Lehiste, 1979: 107):

Avis akvāsas ka
'A sheep and horses'

avis, jasmin varnā na ā ast, dadarka akvams, tam, vāgham garum vaghantam, tam, bhāram magham, tam, manum āku bharantam.

avis akvabhjams ā vavakat: kard aghnutai mai vidanti manum akvams agantam. Akvāsas ā vavakant: krudhi avai, kard aghnutai vividvant-svas: manus patis varnām avisāms karnauti svabhjam gharman vastram avibhjams ka varnā na asti.

Tat kukruvants avis agram ā bhugat.

> 'A sheep on which there was no wool saw horses, one drawing a heavy wagon, another a great burden, and another carrying a human quickly.
> The sheep said to the horses: The heart feels anguish seeing the man driving the horses.
> The horses said: Listen, sheep, the heart feels anguish having seen the man, the master, make the wool of sheep into warm clothes and there is no wool for the sheep.
> Having heard that, the sheep turned away into the field.'

Even aside from the fatal flaws instantly evident to any modern Indo-Europeanist (or, for that matter, to any of the Neogrammarians of the 1870s) – most notably the Sanskrit-like phonology, especially the vowel system, which no one now believes to be possible for Proto-Indo-European (PIE) – Schleicher's fable struck Indo-Europeanists as so unpromising that hardly anybody since then has felt confident enough to reconstruct even a short discourse for Proto-Indo-European (in spite of a few proposed 'updates' of Schleicher's fable, e.g., one by Hermann Hirt in 1938, as cited in Jeffers and Lehiste, 1979: 108). The problem, after the phonology is corrected, is that PIE syntax is too poorly understood to justify constructing PIE sentences. But the issue of whether syntax can be reconstructed at all recurs in the literature of historical linguistics.

Two waves of interest in the topic, one of them widely considered abortive and the other current and growing, account for most of the research. The first wave, which crested in the 1970s, was based on the famous typological morphosyntactic generalizations first presented in Greenberg, 1963. These generalizations focused in particular on clusters of morpheme orderings that tended to appear together as a bundle – for instance, OV word order with postpositions, Adjective-Noun, Determiner-Noun, Relative-Noun, and other word-order patterns. A language in which all the statistically predominant ordering patterns appear together is said (in this view) to be typologically consistent. The fundamental argument relevant to typologically-based syntactic reconstruction is that inconsistencies in ordering patterns, especially as reflected in minor patterns in restricted environments, reflect older consistent patterns, providing a means of reconstructing the earlier morpheme-order patterns. When evidence for certain patterns is lacking (for instance because of the absence of texts in an attested ancient language), the existing orderings, e.g., Noun-Adjective, are used to infer other orderings, e.g., VO word order. In other words, the typological clustering of the various ordering patterns provides directionality of syntactic change and thus permits the reconstruction of earlier syntactic orders.

The most prominent proponent of this approach to syntactic reconstruction is Winfred Lehmann (e.g., 1973, 1974, and see also 1992: 238–240); Lehmann views typologically 'inconsistent' languages – that is, languages that violate Greenberg's ordering generalizations – as predictably transitional, en route to consistency. The entire typological approach to syntactic reconstruction is sharply criticized in Watkins, 1976, with a focus on Lehmann, 1974. Watkins laments the fact that (as he sees it) "the rebirth of Indo-European syntax has taken place in the bed of Procrustes" (p. 305), that "[s]yntax is now viewed as coterminous with word order" (ibid.), and that the approach "elevates some of Greenberg's extremely interesting quasi-universals to the dubious status of an intellectual strait-jacket . . ." (p. 306). He also presents arguments against specific predictions of the typological approach, such as the fact that some typologically 'inconsistent' languages have apparently remained 'inconsistent' for many centuries.

A partly comparable search for universal principles that might lead to valid syntactic reconstruction is Givón's much-cited dictum, "Today's morphology is yesterday's syntax" (1971: 413). Like Lehmann, Givón claims that clues to earlier word-order patterns are to be found in relics, specifically, for Givón, in the order of morphemes in words – the crucial assumption being that processes of cliticization and then affixation of formerly independent words must have fossilized the original relative ordering of the words. This approach too has been sharply criticized (see e.g., Comrie, 1980 and Harris and Campbell, 1995: 199ff.). One empirical problem for the claim is that affixes sometimes change positions in the word relative to other affixes and even relative to the stem, and clitics sometimes change position when they turn into affixes. A major reason for the widespread skepticism about all approaches to syntactic reconstruction that focus on reconstructing word-order patterns is hinted at in one of Watkins' objections: not only is there much more to syntax than word order, but it is also impossible to know, from surface word order alone, the nature of the grammar that produced that word order. So, for instance, a dominant SVO sentential word-order pattern in one language might result from a grammar that specifies SVO word order, but in another language it might result from a verb-second rule.

The search for universals that would permit the establishment of a firm directionality in syntactic change, and thus a sure means of syntactic reconstruction, is continued in some of the research on grammaticalization, and this research goes well beyond word-order studies. Still, proposals of universality have not met with general acceptance. See, for instance, Harris and Campbell (1995: 336–338) for a criticism of claims that certain morphosyntactic changes are predictably unidirectional. Many

linguists, including Harris and Campbell themselves, would agree that a weaker sense of directionality might prove useful in syntactic reconstruction, in the same way that probabilities are used in phonological reconstruction: all things being equal, one would reconstruct **p* rather than **b* for an intervocalic *p : b* correspondence, because intervocalic voicing is more common, and more likely on phonetic grounds, than intervocalic devoicing. Some (not all) of the proposed universals of morphosyntactic change would meet this 'more probable' criterion.

The recent upsurge of interest in syntactic reconstruction is much less homogeneous than the typological approach of the 1970s. Perhaps the most cited recent contribution to the debate, both in its own right and as a stimulus to further research (much of which offers opposing views), is Harris and Campbell's Chapter 12, 'Reconstruction of syntax' (1995: 344–376). Harris and Campbell's approach is criticized in Lightfoot, 2002a, and the discussion is continued in a follow-up exchange (Campbell and Harris, 2002; Lightfoot, 2002b). The two most difficult issues, for syntactic reconstruction in general as well as in these articles, concern the problem of identifying syntactic correspondences in related languages and the problem of directionality. Neither issue is new, but the former in particular has received more attention recently than in (for instance) the 1970s (but see Watkins, 1976).

The crux of the correspondence problem is articulated by Werner Winter (1984: 622–623, and see also the discussions in Harris and Campbell, 1995: 345–353 and Rankin, 2003: 201–206): "Sentences are formed, not learned; morphemes and simple lexemes are learned, not formed." The difficulty is that application of the Comparative Method requires elements that show recurring correspondences in both form and meaning, and in practice this has always meant reconstructing proto-language features on the basis of cognate morphemes – that is, morphemes in two or more daughter languages that are descended from the same morpheme in their shared parent language. The method has been spectacularly successful in the reconstruction of individual morphemes, both words and affixes, and of phonological features abstracted from the reconstructed morphemes; reconstruction of partial morphological patterns has also been carried out successfully, especially where analogic changes that have transformed some daughter-language paradigms are fairly transparent. But purely syntactic structures – those which, unlike constructions that are anchored by such morphemes as the question particle used in the formation of yes/no questions in some language families – offer no cognate morphemes to base a reconstruction on.

As a means of overcoming this difficulty, Harris and Campbell propose the concept of **syntactic correspondence**. Although they acknowledge that "syntax has nothing quite like the duality of patterning (double articulation) in phonology" (1995: 349), they argue that sentences in related languages can be considered to correspond if they mean the same thing and if the grammatical morphemes that are crucially relevant to the structure point under consideration are cognate (p. 349), and if they are "responses to identical or essentially identical stimuli in two stages of a language" (p. 350). This last notion – that identical stimuli can be predicted to produce linguistically equivalent utterances – seems at best overoptimistic; it is surely not supported by psycholinguistic evidence. Harris and Campbell also emphasize that their goal "is to establish correspondence patterns, not corresponding sentences" (p. 350), so in fact their proposal is that there are cognate sentence patterns, not cognate sentences *per se*.

Crucially, they argue for the existence of regularity in syntactic change, equivalent to the regularity hypothesis for phonological change (pp. 326 ff.) – but with a sense of regularity, namely "rule-governed and non-random" (p. 326), that differs sharply from the sense in which phonological change is hypothesized to be regular. An analogic change that levels a morphophonemic stem alternation in an inflectional paradigm is regular in Harris and Campbell's sense, but it is not directly comparable to the concept of regular sound change that has guided applications of the Comparative Method for over a century: regular sound change is form-based only, while analogic change is both form- and meaning-based (as seen, for instance, in certain analogic leveling processes in Serbo-Croatian that affect noun declension but not adjective declension – Thomason, 1976). The morphosyntactic changes discussed by Harris and Campbell in this context are presumably driven by analogy, not by sound change. Another major problem that arises for Harris and Campbell's notion of cognate sentence patterns is the same as a problem noted above for the typological approach to syntactic reconstruction: the same syntactic output in two different languages might well be produced by quite different grammars.

A different line of research aimed at reconstructing syntax focuses on the implications of changes in parameter settings (e.g., Roberts, 1998; Longobardi, 2001; compare the critical discussion in Lightfoot, 2002a: 127–130). But until an approach based on parameter settings is worked out in more detail, including specific examples, the idea is difficult to assess.

Can any safe general conclusions be drawn about the feasibility of syntactic reconstruction? Perhaps.

There is fairly widespread agreement that syntactic identity in all the daughter languages – for instance SOV word order – permits the reconstruction of that pattern in the parent language, and nobody (as far as I know) has recommended that all efforts to reconstruct syntax should be abandoned because they are hopeless. On the contrary, a cautious optimism is widespread and seems justified. Watkins, for instance, argues for the possibility of reconstructing poetic formulas of two and three words – and therefore bits of proto-language syntax – where the formulas are cognate morpheme by morpheme in the daughter languages (1995). Pires and Thomason (forthcoming) argue that, at least at relatively shallow time depths, the Comparative Method can sometimes be used successfully to reconstruct morphosyntactic constructions, for instance the Proto-Romance future (using a deliberately restricted data set for testing purposes); here the analysis rests on shared cognate morphemes, on directional probabilities (clitic-to-affix is more likely than affix-to-clitic), and on drift (independent clitic-to-affix changes in several languages). The prospects seem to be dimmer for successful syntactic reconstruction where the constructions under comparison are not expressed at least in part by cognate morphemes and where there is no identity in all the daughter languages. Certainly proposals that don't meet at least one of these criteria are all highly controversial at present.

Recovery of Language after Stroke or Trauma in Adults

S S Christman and F R Boutsen, The University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA

Introduction

Research efforts in the realm of recovery from aphasia have generally been directed toward (a) identification of salient neurologic and anagraphic factors predictive of recovery, (b) investigation of recovery mechanisms associated with different lesion sites, etiologies, and aphasia symptom clusters using modern imaging techniques, (c) determination of the relative roles of the two cerebral hemispheres in recovery, and (d) explication of the role of behavioral and pharmacological treatments in facilitating recovery from acute, subacute, and chronic aphasia. Current thought on these topics will be discussed herein. Space limitations prohibit discussions of attention, memory, and motor speech recovery, even though deficits in attention and memory may underlie some symptoms of aphasia and even though improvements in all of these domains may parallel and, to some extent, perhaps explain, individual differences in recovery from aphasia (Crosson, 2000a, 2000b; Haarman and Kolk, 1991; Kolk, 1995; Kolk and Weijts, 1996; Tseng *et al.*, 1993). Discussion will focus on recovery from classic acquired aphasia (e.g., that which is associated with CVA or focal trauma) in monolingual speakers rather than recovery from the 'nonacquired' (progressive) aphasias arising from degenerative disease (Kertesz *et al.*, 1994; Mesulam, 1982; Weintraub *et al.*, 1990) or neoplastic proliferation. Recovery phenomena in bilingual speakers with aphasia or in those with crossed aphasia will also not be addressed, though readers are encouraged to investigate these phenomena (cf. Paradis, 2000; Paradis and Goldblum, 1989).

It should be noted that while many acquired aphasic syndromes have been identified and studied in modern research, aphasia is nevertheless a somewhat individualized disorder of impaired information processing, specific to that subsystem of cognition serving language (Davis, 2000; Porch, 1994, 2001). Recovery from acquired aphasia has been thought to depend on a variety of neurological factors, including type of aphasia, severity of initial aphasia, site of neurological lesion, extent of neurological lesion, time postonset, etiology, and presence of concomitant disorders (Basso, 1992). A variety of anagraphic or personal factors such as the age, gender, handedness, and psychosocial characteristics of affected individuals also influences the speed and extent of recovery (Basso, 1992; Hemsley and Code, 1996; LaPointe, 1999). An important additional factor influencing aphasia resolution is the type, frequency, and intensity of speech–language treatment received (Basso, 1992; Carlomango *et al.*, 2001; Weiller *et al.*, 1995). Research in recovery supports the notion of language as a well-distributed function with some localizable aspects, illustrates the limitations of aphasia typologies in capturing recovery phenomena, and establishes the superiority of neurological (vs. anagraphic) factors as those most predictive of recovery. It also pushes the recovery envelope beyond conventional limits by providing evidence for neural reorganization and functional improvement in chronic aphasia when intensive treatment paradigms are applied (Hillis and Heidler, 2002; Pulvermuller *et al.*, 2001).

Aphasia: Localized and Distributed

Aphasia has been defined as "a selective impairment of the cognitive system specialized for comprehending and formulating language, leaving other cognitive capacities relatively intact." (Davis, 2000: 16–17). It is an acquired disorder of language processing arising most often in adults as a consequence of cerebrovascular accident (CVA) or 'stroke' in the language-dominant hemisphere of the brain's cerebral cortex or subcortex (Benson and Ardila, 1996; Brown, 1980; Davis, 2000). There are many types of aphasias, and their symptoms are somewhat predictable from basic principles of brain–language organization. These principles establish that there are strong relationships between normal mental functions (such as language, attention, and memory) and either localized regions of the brain or collections of reciprocal, highly parallel neural networks that are widely distributed across brain regions (Chollet and Weiller, 2000; Howard *et al.*, 1992; Kertesz, 1991; Mesulam, 1990).

Distributed neural networks are comprised of interconnected neurosynaptic circuits, some elements of which may be distant, but all of which converge on local nodal processing zones that are crucial for network operations (Mesulam, 1990). Wernicke's area (minimally Brodmann Area 22 but see Bogen and Bogen, 1976), a region of the cerebral cortex in the superior temporal gyrus of the dominant language hemisphere (the left cerebrum in most individuals) is one such nodal region for the distributed circuitry dedicated to the auditory comprehension of language (Mesulam, 1990). This area also plays an important role in semantic and phonological processing (Kertesz, 1991). Broca's area (typically Brodmann

Areas 44–45), a region of the cerebral cortex in the posterior, inferior area of the third frontal convolution of the dominant language hemisphere, is another nodal region whose function is essential for motor speech planning/programming (Mesulam, 1990; Van der Merwe, 1997), for some forms of semantic processing, and for some aspects of syntax construction and interpretation (Kertesz, 1991). Wernicke's and Broca's regions are frequently coactive during language processing (Van der Merwe, 1997) and, when damaged, frequently lead to distinctly different but persistent symptoms of aphasia. Damage to the more widely distributed elements of the auditory comprehension or syntactic processing circuitries may also impair the adequacy of those functions but usually not to the extent that is found when damage to the nodal (Wernicke's or Broca's) zones occurs (Mesulam, 1990).

Other important speech and language processing circuits support those associated with Wernicke's and Broca's areas and yield aphasic outputs when damaged. Individual differences notwithstanding, strokes involving large portions of the frontal language cortex (especially Broca's area, or zones anterior–superior to or deep to Broca's area), and/or portions of the basal ganglia typically cause the so-called 'nonfluent' types of aphasia such as Broca's aphasia, transcortical motor aphasia, mixed transcortical aphasia, global aphasia, and striato-capsular aphasia (Benson and Ardila, 1996; Goodglass and Kaplan, 1983; LaPointe, 1997). These disorders may vary somewhat in severity and symptomatology, but as a group they are characterized by nonfluent speech, relatively few phonemic paraphasias (sound substitutions, omissions, additions, or misorderings), difficulty accessing content words (particularly verbs), and disturbed comprehension and production of complex syntactic forms. Sentence production is usually described as telegraphic or agrammatic, lacking intact syntactic constituent structures and characterized by the omission of free and bound grammatical morphemes (Berndt, 1998; Caplan, 1987, 1992; Kean, 1985; Kearns, 1997).

Strokes involving posterior cortical language zones (especially Brodmann Areas 22, 37, 39, 40) and/or the thalamus, on the other hand, frequently cause the more 'fluent' aphasias such as Wernicke's aphasia, transcortical sensory aphasia, conduction aphasia, anomic aphasia, and thalamic aphasia (Benson and Ardila, 1996; Goodglass and Kaplan, 1983; LaPointe, 1997). These disorders frequently are identified by impaired auditory comprehension, severe word-finding deficits (particularly for nouns), copious production of phonemic paraphasias and neologisms, and syntax production deficits characterized by substitutions (more often than omissions) of free and bound grammatical morphemes (Benson and Ardila, 1996; Buckingham, 1989; Caplan, 1987, 1992; Christman and Buckingham, 1989; Gonzales-Rothi, 1997; Simmons-Mackie, 1997). Recovery from aphasia is an incremental process characterized by a reduction of symptoms and an improvement in language comprehension, production, or integration.

Discussions of recovery from aphasia frequently link physiological and behavioral concepts, inadvertently suggesting that localizing and/or measuring changes in the activity of normal and lesioned brain areas is akin to localizing and/or assessing improvements in normal and disordered mental functions. John Hughlings Jackson (1874), however, cautions otherwise (Kertesz, 1991) as do Chollet and Weiller (2000: 587) who note that, "... recovery corresponds to improvement of clinical function in patients and not necessarily to any changes in cerebral activation patterns as they can be observed with modern neuroimaging techniques." It is therefore important to be careful in the attribution of causality to any of the neurological changes accompanying functional improvements in aphasia. It is a *sine qua non* in the philosophy of science that 'correlation' does not and cannot mean 'causation.' Despite this caveat, a thriving line of research suggests that neural reorganization and reduction in aphasia symptoms may correlate even in patients with chronic aphasia (Pulvermuller *et al.*, 2001).

While there are correlations between specific brain areas and associated linguistic functions, there is sufficient functional overlap or redundancy in distributed language processing networks to permit several different neural structures to perform a particular operation on different occasions (Kertesz, 1991). One such occasion may be when brain damage provides an opportunity for nonnodal, or even latent, circuits to assume (albeit less efficiently) the function of a damaged network (Chollet and Weiller, 2000) during recovery. Localizing function is perhaps least controversial for nodal brain areas but even then, functional localization is not fixed because the brain retains some plasticity or capacity for reorganization across the lifespan (Brown, 1980, 1982; Chollet and Weiller, 2000). The extent to which portions of nodal zones can recover function, the extent to which distributed (nonnodal) network circuitry can continue a function, and the extent to which nondedicated or formerly nonparticipatory circuits can assume new functions comprise some of the issues investigated in the research on the neural mechanisms underlying recovery from aphasia.

Recovery: A Continuous Phenomenon

A Framework for Understanding Recovery

Recovery from acquired aphasia is evident when language processing skills improve to levels beyond those extant immediately after the onset of stroke. Recovery is therefore defined operationally in behavioral terms and cannot be directly attributed to specific changes in poststroke neurophysiology (Chollet and Weiller, 2000; Porch, 1994, 2001). Porch (1994: 175) described aphasia from this kind of cybernetic perspective, arguing that neurological insults reduce the brain's ability to,

> "store, switch, and monitor, and to do the many other steps necessary for the brain to receive, assimilate, and send information. Since these processes cannot be observed directly, they must be assessed by exposing the patient to standard tasks . . . and then the clinician, by carefully noting the response characteristics of the patient, can make inferences about the relative efficiency of various 'brain circuits.'"

This approach views aphasia less as a loss of morphosyntactic, semantic, and phonological knowledge per se and more as a disorder of an individual's ability to accurately, responsively, completely, promptly, and efficiently utilize the computational processes underlying language processing (Porch, 1994, 2001). Computational failures of these kinds lead to the types of linguistic errors (e.g., semantic or phonemic paraphasias, agrammatic or paragrammatic syntax), comprehension deficits, response delays (e.g., long or short, filled or silent latencies), and unintelligible utterances (e.g., neologisms) that characterize the aphasias. In this paradigm, recovery is observed when language tasks are processed more accurately, responsively, completely, promptly, and efficiently than they were previously. Therapeutic improvement is accomplished by repeatedly stimulating damaged language systems with performance tasks that are challenging but achievable (Porch, 1994, 2001; Schuell, 1974). The assumption underlying this approach is that when damaged neural networks are properly stimulated, repeated activation of those networks ultimately increases their internal activation strength, in consequence yielding faster and more accurate language processing over time. Many current models of parallel language processing in artificial intelligence systems support this conclusion (cf. Martin and Dell, 2004), but the precise nature of the brain–language interface remains elusive. To the extent that the cybernetic metaphor can be extended to actual neurological activity, however, this remains the fundamental principle underlying recovery from aphasia.

As Kertesz (1988) affirms, aphasia is a dynamic disorder, a disorder in evolution. When aphasia is viewed as a constellation of symptoms, with each symptom moving along an independent recovery continuum over time, it is not surprising that chronic symptom profiles may differ significantly from acute symptom profiles. Aphasia taxonomies are problematic for representing the nature of change underlying aphasia recovery, because their use suggests that aphasic speakers somehow metamorphose from one type of aphasia to another (from Global to Broca's type, for example). A more logical conceptualization is that initial poststroke phenomena such as edema and diaschisis compromise the function of multiple local and distant circuits within the language processing network, and across related networks, yielding numerous initial symptoms that may not persist over time. Diaschisis, the state of 'shock' into which hypoperfused neurons enter after a brain injury, spreads along neuroanatomical pathways away from an initial site of lesion, reducing function in the many brain areas that may be served by those pathways (Chollet and Weiller, 2000). Cerebro-cerebellar connections, for example, allow damage to the cerebrum to suppress metabolic function in remote cerebellar locations. Although the relationship between diaschisis and aphasic symptoms is not fully understood, it is suspected that as edema and diaschisis resolve during the process of spontaneous recovery, some initial symptoms of aphasia will disappear (Cappa, 2000). As language processing networks are stimulated through use, a number of neural mechanisms may contribute to improved processing over time. As Rosenbek *et al.* (1989) note, however, a core of aphasia symptoms will persist in most individuals.

The principle that local neural networks participate in larger-scale networks is consistent with the observation that diverse lesion sites (affecting diverse neural networks) can yield similar symptoms (e.g., naming is mediated redundantly across right and left peri-Sylvian cortex, as well as across some subcortical structures, so anomic behavior arises unsurprisingly from lesions to multiple cortical and subcortical sites). Individual differences in language network configurations may be genetically coded, may reflect neural reorganization following cortical injury, may depend on the age at which a language was learned, and may depend on an individual's gender, handedness, or intrinsic learning style. Individual differences suggest the likelihood that identically located lesions across individuals may not yield identical symptom complexes, and suggest the converse as well – that different lesion sites across individuals may occasionally yield similar symptom complexes (Kertesz, 1991). These factors confound the study of recovery

in aphasia, making it difficult to match subjects in group studies, but also making it difficult to generalize findings from single subject studies where an individual subject has been his own control. These methodological difficulties, combined with the ambiguities inherent in typology change over time, make it difficult to compare studies of recovery. Nevertheless, a review of the recovery literature suggests that there are some factors that can reliably predict recovery from aphasia.

The Aphasia Recovery Curve

The classic recovery curve in aphasia can be described as one of gradual inclination and progressive deceleration within the first year postonset (Porch, 1994, 2001). Although there is little agreement as to the exact time course for recovery, the greatest improvement in language function is generally seen within the first three months postonset (Kertesz, 1988). Although some have suggested that little change in language function will occur past that time (Basso, 1992), recent studies suggest otherwise (Pulvermuller *et al.*, 2001). Recovery plateaus are generally apparent within six months to one year postonset. The parallel of the aphasia recovery curve with that of spontaneous (biological) recovery has prompted numerous aphasia treatment studies (Basso, 1992), many of which suggest that language recovers best in response to purposeful, intensive stimulation, whether delivered by educated professionals or caregiving significant others. Other studies, however, have shown that many patients with aphasia recover functional language even without directed intervention (Basso, 1992).

Different recovery mechanisms may be at work at different overlapping 'stages' of the recovery continuum. While neural reorganization can occur soon after stroke, especially with peripheral or small cortical lesions (Chollet and Weiller, 2000; Merzenich *et al.*, 1983; Coq and Xerri, 1999; Jenkins and Merzenich, 1987; Jenkins *et al.*, 1990; Weiller *et al.*, 1992). Hillis and Heidler (2002) suggest that this, together with the learning of compensatory strategies, is more likely a mechanism associated with later stages of recovery from aphasia. They further suggest that it is the reperfusion of surviving (but nonfunctional) ischemic tissue surrounding an area of infarct (i.e., reperfusion of the 'ischemic penumbra') that probably accounts for early resolution of aphasic symptoms, even in severe cases, during the first few (1–3) days following stroke. To test this premise, Hillis and Heidler (2002) investigated early recovery of lexical-semantics (reflected via spoken word comprehension) in 18 patients with aphasia secondary to posterior left hemisphere stroke. They hypothesized that if initial hypoperfusion of Wernicke's area causes poor word comprehension, speedy reperfusion of that area should accompany improved comprehension soon after stroke.

Patients meeting the criteria for lexical-semantic deficit (10 men, 8 women, all right-handed, mean age 61 years) were assessed once with magnetic resonance imaging techniques of perfusion-weighted imaging (PWI) and diffusion-weighted imaging (DWI) at Day 1 of stroke onset and again at Days 2–5 (mean Day 3) postonset. Perfusion levels of ten anterior and posterior left hemisphere cortical zones (Brodmann Areas 10/11, 18/19, 20, 22, 37, 38, 39, 44, 45) were evaluated on each assessment. Lexical-semantic tasks (word comprehension and production) were given on Day 1 and at follow up. Thirteen of the eighteen subjects demonstrated early recovery of lexical-semantics. All 13 of these subjects showed a corresponding statistically significant reperfusion of Area 22 (Wernicke's area) to the exclusion of the other Brodmann areas studied. None of the five subjects with poor lexical-semantic recovery demonstrated reperfusion of Wernicke's area. This double dissociation, and in the coincident absence of evidence for neural reorganization in subjects studied, suggests a crucial role for reperfusion of an ischemic penumbra (in this case, Wernicke's area), in early recovery of lexical-semantics in aphasia.

Hillis and Heidler (2002) argued that whereas rapid neural reorganization has been documented in the sensory cortex following peripheral limb amputation and in the sensory-motor cortex following small focal lesions, less rapidity is observed when cortical lesions are large and/or when damaged functions (such as lexical-semantic processing) are complex and widely distributed. They suggested that in most cases of aphasia, recovery can be characterized as a three-stage process mediated by different neurological mechanisms and benefiting from different approaches to intervention. The first, acute, phase of recovery occurs during the first few days after stroke and is characterized primarily by reperfusion of the ischemic penumbra and/or reduction of diaschisis (Cappa, 2000). Intervention at this stage of recovery is best managed medically with input provided to patients and families from speech-language pathologists who can share information and counseling with regard to the nature of recovery from aphasia. The second or subacute stage of recovery may begin several days after onset and continue for months or even years. Neural reorganization is thought to account for most aspects of recovery at this stage and rehabilitation efforts are directed toward the provision of intensive therapies for language stimulation.

The third or chronic stage of recovery follows the completion of neural reorganization and probably involves the establishment of new pathways to link language processing zones that have become functionally disconnected as a consequence of stroke. In the chronic phase of recovery, speech-language intervention may yield improved behavioral outcomes in motivated patients who receive intensive daily treatment and/or who are receptive to learning compensatory strategies for managing compromised language skills (Hillis and Heidler, 2002; Pulvermuller *et al.*, 2001). As Hillis and Heidler, (2002: 893) noted, "These stages are likely overlapping, in that one language function might be recovering in one stage, while another language function is recovering in another stage, in the same individual." This phenomenon explains why some patients initially diagnosed with one type of aphasia, such as Wernicke's or conduction aphasia, may eventually recover to another type such as anomic aphasia, the residual symptom profile apparent when, for example, initial auditory comprehension problems, phonemic jargon, and verbal repetition deficits improve but aphasic word finding difficulties persist (Simmons and Buckingham, 1992).

Neurologic Factors in Aphasia Recovery

Mechanisms of Recovery

The mechanisms of neurological change during recovery from stroke are thought to contribute to recovery from aphasia, although the degree of causality remains unclear (Cappa, 2000; Cappa *et al.*, 1997). Chollet and Weiller (2000) described four mechanisms of cerebral reorganization made apparent from a decade of poststroke neuroimaging studies: spontaneous neural reorganization, recruitment of remote brain areas (including the cerebral hemisphere contralateral to the site of stroke), extension of specialized areas into neighboring cortex, and increased neurological activity in lesioned areas. Spontaneous neural reorganization in stroke patients can be observed with Positron Emission Tomography (PET) as changes in patterns of cerebral metabolism (increased and/or decreased) relative to patterns exhibited by normal controls (Weiller *et al.*, 1992). Metabolic changes unrelated to diaschisis can be observed soon after stroke onset and may account for the rapid improvement seen in the postacute phase of recovery from aphasia (Chollet and Weiller, 2000). PET studies have provided some evidence that the right hemisphere (remote to lesioned left temporal cortex) is activated during language processing in patients with good (vs. poor) recovery from Wernicke's aphasia (Weiller *et al.*, 1995), although studies have also shown that some normal, nonaphasic individuals show right hemisphere activation during similar language tasks (Frackowiak, 1997). With regard to cortical extension, it has been well-documented that lesions to motor pathways and the motor cortex can influence the activity of undamaged motor zones. Cortical areas that have become underactivated because of limb paralysis, for example, may become rededicated to the function of remaining intact limbs or other moveable structures that are represented nearby on a cortical motor map (Cohen *et al.*, 1991; Nudo *et al.*, 1996; Weiller *et al.*, 1992; Weiller *et al.*, 1993; Pons *et al.*, 1991). Finally, with regard to increased activity of nonspared cortical areas, evidence suggests that, at least with regard to the hierarchically organized motor system, damage to lower-order structures leads to increased compensatory activity of associated higher-order structures in the system. It is interesting to speculate that a highly integrated but nevertheless hierarchically conceived language system (cf. Brown, 1982) might show much the same pattern of neural reorganization after stroke.

This observation is consistent with Melulam's assertion that distributed activation networks can demonstrate spontaneous learning and is certainly consistent with the work of Mazzoni and colleagues (1992), who were able to quantify spontaneous recovery from aphasia in 45 first-time stroke patients. Assessments of oral and written expression, as well as auditory–verbal and reading comprehension were conducted at 15 days postonset, one month postonset, three to four months postonset, and six to seven months postonset.

Mazzoni *et al.*'s (1992) findings across subjects, in summary, were the following:

1. Oral comprehension recovery began early at two weeks postonset, continued throughout the first year after stroke, and was independent of initial aphasia type, severity, or size of lesion. Reading comprehension was maximal within the first month postonset.
2. Recovery rates for expression were slower than for comprehension and differed according to aphasia type. Fluent aphasias showed uniform improvement from two weeks postonset onward; nonfluent aphasias began to improve only at the three to four month poststroke period. Apraxia of speech may have confounded results in the latter group.
3. Fluent patients and all patients with moderately severe aphasias improved significantly in all four language modalities (verbal expression, listening comprehension, reading, writing). Nonfluent

patients and those with initially severe aphasias showed limited improvement in verbal expression and no recovery of written language.

4. Patients with small lesions of moderate size showed significant recovery across modalities. Patients with moderately sized lesions improved in all modalities except written expression. Patients with large lesions only showed improvement in auditory comprehension.

Their main conclusions were that (1) the dominant language hemisphere has good potential for assisting with auditory comprehension but not verbal expression, and that (2) the posterior site of lesion correlates with increased aphasia severity, which in turn predicts poor recovery. Because auditory comprehension deficits frequently characterize the posterior aphasias, the findings of Mazzoni and colleagues present aphasiologists with a conundrum for future study.

The Role of the Contralateral Cortex in Recovery

There are many approaches to measuring the role of the cerebral hemispheres in the recovery from aphasia. According to Cappa and Vallar (1992), the most widely used physiological approach to lateralization studies is examination of auditory evoked potentials to linguistic stimuli. Thomas *et al.* (1997) suggested that electroencephalography (EEG) provides a reliable and robust method for assessing changes in lateralization of language functions during recovery, and Cappa (2000) noted the important role that Positron Emission Tomography (PET) and functional Magnetic Resonance Imaging (fMRI) technologies have played in recent aphasia studies. Recovery research varies across a number of important factors, including subject characteristics (e.g., subject age, language, etiology), numbers of subjects per study, type of aphasia examined, nature of symptoms tested, stage of recovery studied, and method of brain assessment used, among others. This variety creates difficulties in the comparison of findings across studies, but there are nevertheless some general (occasionally conflicting) conclusions that can be drawn about the role of the two cerebral hemispheres in recovery from aphasia. They may be summarized as follows: right-hemisphere activity in areas homologous to damaged left-hemisphere zones is frequently observed early in recovery for both anterior and posterior language zones. In later stages of successful recovery, increased activity in damaged left-hemisphere zones, with concommitant diminution of right-hemisphere activation, is often apparent, especially in frontal language areas (Thomas *et al.*, 1997). With temporal-parietal damage, however, a pattern of persistent right-hemisphere activation, even amidst increased left-hemisphere activity, is frequently present in aphasic patients regaining auditory comprehension and semantic processing skills (Thomas *et al.*, 1997; Weiller *et al.*, 1995). At the very least, these principles suggest the desirability of ipsilateral recovery after left-hemisphere damage, but they do not clarify the role of contralateral hemisphere activity during recovery from left-hemisphere damage (Cappa, 2000).

It has been suggested that novel right-hemisphere activity subsequent to left-hemisphere aphasia reflects a variety of possible favorable and nonfavorable behavioral and/or neurological phenomena including, (a) compensatory language processing activity via activation of latent language-capable circuits, (b) disinhibition of the contralateral cortex resulting in 'maladaptive' functional reorganization, and (c) recruitment of additional cognitive resources (attention, memory) to those normally needed for language processing (Belin *et al,*, 1996; Cappa, 2000; Thomas *et al.*, 1997; Weiller *et al.*, 1995).

The work of Papanicolaou and colleagues (1984, 1987, 1988) has shown that chronic aphasics (with LH language dominance) show a larger right-hemisphere response to language stimuli than do either normals or right-hemisphere impaired subjects. Computerized Axial Tomography (CAT) and regional blood flow studies conducted by Knopman (1984) have shown increased and extensive activation of the right-hemisphere cortex during listening tasks at six months (compared to three months) postonset for aphasic speakers who had sustained damage to the left temporoparietal cortex and who still presented with partial deficits in auditory comprehension. Conversely, their subjects whose left-dominant auditory association cortex was spared and who had recovered completely from initial auditory comprehension deficits, showed the predicted left posterior pattern of activation for listening tasks. These findings indicated that for the latter subject group, early comprehension impairments and their resolution were most likely due to disruption and then recovery of ipsilateral neural networks distant to the focal site of lesion. For the former subject group, however, structural damage to left hemisphere local networks dedicated to auditory comprehension precluded recovery of function by that region. Partial functional recovery in their case depended upon assumption of function by capable and diffuse, but less efficient, neural networks in the contralateral hemisphere.

When these studies are compared with those evaluating recovery of frontal function, and in particular, recovery of speech fluency (Vallar *et al.*, 1988), it would seem that the undamaged left- rather than the right-hemisphere cortex is primarily responsible for recovery from nonfluent aphasia (and perhaps

associated speech apraxia). This conclusion is supported by the work of Thomas *et al.* (1997) whose EEG studies of eleven patients with Broca's and Wernicke's aphasias showed an initially right-hemisphere activation pattern in Broca's aphasia shifting with increased recovery to a left-hemisphere frontal pattern. Their patients with Wernicke's aphasia, on the other hand, showed a permanent right-hemisphere shift for tasks in which all patients (fluent and nonfluent) had to search for synonyms to orally presented nouns. Other case studies, however, such as those conducted by Thulborn and colleagues (1999), cited MRI findings to suggest that nonfluent Broca's and fluent Wernicke's aphasias both recover auditory comprehension skills via increased and persistent activation from right-hemisphere homologous zones. Again, differences in subject and methodological variables may account for differences in findings across recovery studies.

The time course for assumption of function by the nondominant cortex for lexical-semantic tasks is not known, although the work of Demeurisse and Capon (1991) has suggested that significant right-hemisphere activity can be observed at three months postonset and Thulborn *et al.* (1999) have suggested that it can be detected at three days poststroke. Bushnell *et al.* (1989) have determined by Single Photon Emission Computerized Tomography (SPECT) analysis that extensive left-hemisphere hypoperfusion at one month postonset correlates inversely with degree of recovery at three months postonset. Interestingly, a SPECT study of subcortical aphasia by Vallar *et al.* (1988) has shown that reduced left-cortical hypoperfusion correlates with poor language recovery, suggesting that hemispheric mechanisms mediate recovery from subcortical, as well as cortical, aphasias. Cappa and Vallar (1992) suggest the superiority of Positron Emission Tomography (PET) scanning as the method of choice for investigating neurological correlates of recovery, but cite PETs limited availability as problematic.

One study that challenges the aforementioned conclusions about cortical neurophysiology and recovery, however, has employed PET technology to evaluate whether improvements in auditory comprehension can be linked to improvements in right or left temporoparietal regional glucose metabolism after stroke. Metter *et al.* (1992) evaluated eight right-handed male subjects who sustained single vascular lesions (sites not given), who had no previous histories of stroke, and who originally presented a variety of mild to severe aphasias. Each patient was scanned twice, first at one month postonset, and again at no sooner than six months postonset. Results showed that six of the eight patients showed improved left-hemisphere temporoparietal glucose metabolism, although the amount of improvement varied across subjects. The highest metabolism rates were found for Wernicke's regions rather than for parietal zones in the six improved subjects. Increased glucose metabolism was also observed in these subjects across the right-hemisphere cortex, with increased metabolism of the right-temporoparietal cortex correlating significantly with left homologous zones. Metabolic findings correlated closely with improved scores on the *Western Aphasia Battery* (WAB) (Kertesz, 1982). Assuming (cautiously) that metabolic change over time may reflect change in brain function, Metter *et al.*'s (1992) findings support the general hypothesis that recovery of comprehension is dependent on recovery of, and/or assumption of function in, the left and right posterior cortex. The contributions of left- and right-hemisphere recovery may not be independent, but may, "interact in such a way as to facilitate the recovery of comprehension" (Metter *et al.*, 1992: 357).

Ansaldo *et al.* (2002) concur that both cerebral hemispheres contribute to recovery from aphasia, though not necessarily at the same time nor to the same degree. In a case study of a young woman with Broca's aphasia secondary to a left fronto–parietal hematoma, Ansaldo and colleagues examined the role of the right and left hemispheres in the processing of nouns and verbs of high and low imageability. A computer-driven lexical decision lateralization task allowed the experimenters to determine that by four months after the onset of Broca's aphasia, the right hemisphere participated more than the left in the comprehension of highly imageable nouns and verbs. By eight months postonset, the right hemisphere was additionally active in the recognition of low imageability words. By a year postonset, however, no distinct lateralization pattern was apparent; the left and right hemispheres participated equally in lexical decision tasks, and oral expression began to show considerable improvement as well. The authors suggest that, in accordance with findings by Karbe *et al.* (1998), right-hemisphere compensatory activity is needed less over time as impaired left hemisphere processing slowly improves (see Cao *et al.*, 1999). Results also point to the recovery of the left-hemisphere Broca's area in the improvement of verbal expression.

If verbal expression depends on sufficient amounts of left-hemisphere frontal cortex for recovery, then large lesions will yield initially severe nonfluent aphasias that will not ameliorate; if large lesions destroy significant amounts of left temporoparietal cortex, the potential for recovery of auditory comprehension is good with right hemisphere assumption of function. However, among even the most severe of

nonfluent aphasias, global aphasia, different recovery profiles can be seen (Ferro, 1992). In a CAT study of 54 Portugese, right-handed, firsttime stroke patients, Ferro (1992) showed that five different lesion locations yielded acute global aphasia: (1) large fronto–temporo–parietal lesions, with or without subcortical extension, (2) anterior, suprasylvian, frontal lesions with or without subcortical damage, (3) large subcortical infarcts, (4) posterior, suprasylvian, parietal infarcts, with or without subcortical extension, and (5) a double lesion composed of a frontal and a temporal infarct. Although patients with lesions from the first location tended to have initially more severe aphasias than patients with the other four lesion loci, language and neuropsychological profiles conducted at one month postonset revealed similar functional profiles across all five groups. By six months postonset, recovery profiles revealed that (1) patients with the first type of lesion had the poorest prognosis, retaining global aphasia and showing limited improvement, (2) patients with lesion locations 2, 3, and 4 showed variable degrees of recovery, improving to Broca's or transcortical aphasia or showing only anomic or speech apraxia deficits, (3) patients with exclusively deep lesions had the best prognosis and some with subcortical and anterior infarcts recovered completely, and (4) patients with lesion location number 5 showed only modest improvement (Ferro, 1992: 427). Ferro noted that while other anatomical sites may also yield global aphasia, his groupings were notable for the similarity of symptoms across groups and the differential recovery patterns identifiable by group, despite the diversity of lesion sites. Ferro (1992) specifically addressed the compatibility of his findings with those of Mesulam (1990), whereby anatomically diverse lesions to a large-scale distributed network, such as that subserving language, are quite capable of yielding transient and relatively similar-looking dysfunctions of the whole network. Further, unless the system sustains massive damage, or damage to a completely dedicated (or modular) local component, recovery should be expected if sufficient stimulation is provided to the damaged processing system.

Anagraphic Factors in Aphasia Recovery

With regard to anagraphic, or personal history, factors, Basso (1992, 2003) suggests that handedness, gender, and even age are not significant prognostic factors. In her recent text *Aphasia and Its Therapy*, Basso (2003: 192) examines the factors influencing recovery and states that, "To my knowledge, no study has tackled the problem of the possible influence of personal factors (age, sex, handedness, and educational level) on the effect of rehabilitation. However, they have been studied in relation to spontaneous recovery and . . . we can safely conclude that the most recent investigations have not demonstrated that they have an important role in recovery (for a review, see Cappa, 1998)." Part of the difficulty in establishing the positive contribution of personal factors to recovery is that it is difficult to isolate them as causative influences in recovery studies. There may be an interaction, for example, between age, aphasia type, and severity of aphasia. An interesting demographic reviewed by Coppens (1991) reveals that Wernicke's aphasia (a frequently severe aphasia associated with poorer recovery than Broca's aphasia (Kertesz, 1988)) is linked more often to older individuals, whereas Broca's aphasia occurs more frequently in younger patients. Although the reason for this remains unclear, common sense would suggest a generally poorer prognosis for older patients due to the increased likelihood of concomitant disease in that population.

The Role of Rehabilitation in Recovery

There appears to be some direct evidence that neural reorganization and functional recovery from aphasia are linked, particularly when reorganization is induced by language rehabilitation training. Further, it appears that neural changes can occur and be detected within minutes of training. Musso and colleagues (1999) studied four stroke patients with auditory comprehension deficits and left hemisphere Wernicke's aphasia in order to address these issues. Assessments of auditory comprehension skills (using a short form of the *Token Test*) were obtained during each of 12 consecutive PET scans, after each of which patients underwent intensive eight-minute language comprehension training sessions. Training-induced improvements on *Token Test* performance were noted across scanning sessions and were correlated with increased activity of the posterior portion of the right superior temporal gyrus and the posterior portion of the left precuneus in subjects studied, suggesting a role for the right hemisphere in recovery from left hemisphere Wernicke's aphasia.

It should be noted that the language training activities used by Musso *et al.* (1999) included five different comprehension tasks presented in varying order and at increased levels of complexity on successive training trials. Tasks required patients to perform actions with objects, to match pictures with objects, to evaluate the semantic correctness of sentences, to evaluate the phonological correctness of sentences, and to match pictures with descriptive sentences. The training tasks tapped into a number of the

component linguistic processes and input/output modalities (e.g., auditory, visual, tactile) involved in language comprehension, processes whose supportive circuitries are normally distributed across many regions of the left and right cerebral hemispheres (especially with regard to semantics). The increasing complexity of the assessment and training tasks across time also placed considerable demands on patients' attention and memory systems, some aspects of which are thought to be mediated by the right hemisphere. Musso and colleagues raise an important point as they interpret their findings: the right-hemisphere activity they recorded might reflect that hemisphere's contribution to language comprehension *per se*, or it might reflect its role in short-term verbal memory (Paulesu *et al.*, 1993), a deficit in which may contribute to aphasic language comprehension impairments (Wilson *et al.*, 1989; Wilson *et al.*, 1995; Hermann, 1992). It is also difficult to know whether the increase in posterior right-hemisphere activity during repeated testing really reflects right-hemisphere activation or left-hemisphere inhibition of right-hemisphere activity, a point that emphasizes the complex nature of language processing across disparate brain areas (Thomas *et al.*, 1997).

Important advances in the treatment in chronic aphasia suggest renewed hope for individuals in whom fluent or nonfluent aphasia has persisted beyond six months postonset. A novel treatment approach dubbed Constraint-Induced Movement Therapy ('CI therapy') has been shown to be effective in improvement of poststroke limb motor skills (Duncan, 1997; Leipert *et al.*, 2000) and may have beneficial application in aphasia rehabilitation. Constraint-induced therapy appears to foster neural reorganization in impaired limbs. Soon after stroke, there is frequently a decrease in the cortical representation of limbs having paralyzed or disused muscles; restraining intact limbs while forcing impaired limbs to perform premorbid functions seems to yield an improved representation of damaged limbs and facilitate neuroplastic changes associated with improved use of those structures (see Liepert *et al.*, 2000 for review).

Part of the beneficial effect of CI therapy for improvement of motor skills may be attributed to the brief but intensive structure of the therapy design (e.g., restraint of a nonaffected limb for 90% of waking hours across 12 days of treatment, 8 days of which also included six hours of behavioral training in the use of the nonrestrained affected limb) (Leipert *et al.*, 2000). While the application of this model to aphasia rehabilitation is somewhat awkward, it has proven useful in the few studies conducted to date. One of the most compelling of those studies was conducted by Pulvermuller *et al.* (2001) with 17 right-handed (three premorbidly ambidextrous) aphasic stroke patients who were monolingual speakers of German. Patients had sustained focal lesions in the territory of the middle cerebral artery; most were diagnosed with Broca's aphasia but four patients exhibited Wernicke's aphasia and three patients exhibited other types of aphasia (transcortical, conduction, and anomic types). The 17 predominantly male subjects with aphasia were randomly assigned to either a constraint-induced treatment group (N = 10; five with moderate aphasia, three with severe aphasia, two with mild aphasia; six with Broca's aphasia, two with Wernicke's aphasia, one with transcortical aphasia, one with anomic aphasia; mean age = 55.4 yrs; mean time postonset = 98.2 months) or a conventional treatment group (N = 7; four with moderate aphasia, one with severe aphasia, two with mild aphasia; four with Broca's aphasia, two with Wernicke's aphasia, one with conduction aphasia; mean age = 53.9 yrs; mean time postonset = 24.0 months). Both treatment groups received the same total amount of therapy time, although the delivery structure was organized differently per group: the CI therapy group received 3–4 hours of speech–language therapy per day for 10 days (mean hours of treatment = 31.5), whereas the conventional treatment group received an equivalent number of treatment hours (mean = 33.9) distributed across 3–5 weeks.

The treatment approach used with the CI group was similar to that of the PACE (Promoting Aphasics' Communicative Effectiveness) method (for a description, see Davis and Wilcox, 1985), where speakers must communicate effectively across a barrier about a hidden referent (picture or object). Importantly, and unlike the conventions of PACE therapy, patients with aphasia in the CI group were required to use only verbal communication, the modality that was most difficult for them after the onset of aphasia. They were required to perform systematic massed practice of speech acts that were extremely difficult for them, and they were not allowed to use compensatory techniques or other communicative modalities that would more easily allow them to exchange information. Patients assigned to the conventional treatment group received intervention described by Pulvermuller *et al.* (2001) as a syndrome-specific standard approach to aphasia rehabilitation based on classic principles established by Hildred Schuell (1974) and targeting skills in naming, verbal repetition, sentence completion, following instructions, and conversation.

The results of the Pulvermuller *et al.* (2001) study revealed that subjects in the CI treatment group performed significantly better on a posttreatment

administration of the *Aachen Aphasia Test* (Huber *et al.*, 1983) than did the subjects in the conventional treatment group. The CI subjects also appeared to have a greater improvement in everyday communication skills than did subjects in the conventional treatment group. This finding was particularly intriguing given that the subjects in the CI treatment group had, on average, exhibited chronic aphasia for almost four times the average duration of that of the conventional treatment group. It is not often the case that patients with moderate-severe aphasia improve so rapidly during the course of treatment. More typical is the Pulvermuller *et al.* (2001) finding for the subjects in the conventional treatment group, where no significant gains in language performance were apparent during therapy posttesting.

Pulvermuller and colleagues (2001) were careful to note that the design of their study did not allow them to determine whether the most beneficial treatment factor for patients in the CI group was the massed practice component, the constraints on responding to treatment stimuli, or the apparent communicative relevance of the therapeutic tasks. They did suggest, however, that the combination of all three may stimulate neural mechanisms underlying brain plasticity, heretofore suppressed by learned nonuse of verbal language, to aid recovery even in people whose aphasia had lasted, on average, eight or more years. Whether these results can be generalized to other patient populations (such as those who are older) is not known.

New behavioral treatment paradigms such as constraint-induced therapy or computer-assisted interventions (Aftonomos *et al.*, 1997) give hope to individuals with chronic aphasia – those who have traditionally been advised that recovery stops after six months to a year postonset. Another exciting trend with the potential to improve recovery is the pharmacological management of acute, subacute, and chronic aphasia, especially when such potentially useful medications as piracetam, bromocriptine, and dextroamphetamine, among others, are combined with speech–language therapy. The following recent sources provide more information on this topic: Bragoni *et al.* (2000), Deberdt, (1994), Greener *et al.* (2001), Huber (1999), Muller and von Crammon (1994), Troisi *et al.* (2002), Walker-Batson *et al.* (2001).

Conclusion

Research investigating the mechanisms of recovery in aphasia proceeds from several different and occasionally overlapping lines of evidence: neuroimaging studies, lateralization studies, and treatment studies. Each approach provides a unique perspective on the reemergence of language function after stroke, but some conclusions can be drawn from findings across various types of studies. Basso (1992) acknowledged the interdependence of lesion site and size with aphasia type and initial severity, and suggested the superiority of initial severity for predicting aphasia prognosis. She noted that traumatic aphasia generally has a better prognosis than vascular aphasia, and that among vascular etiologies, hemorrhage generally predicts the poorest recovery.

Whereas improvement can generally be predicted for aphasic speakers as a group, it is relatively difficult to predict recovery for individual patients, especially during the acute (two weeks postonset) period of illness; findings are mixed as to whether outcome severity can be predicted well during the acute phase of aphasia (Wallesch *et al.*, 1992). Initial communication ratings for spontaneous speech may be more reliable than semantic, syntactic, or phonological factors in outcome prediction: poor initial communication abilities may predict poor recovery, because impaired communication suggests the presence of other limbic, reticular, and/or cognitive deficits that, if present, would exacerbate an aphasia.

Initial severity of aphasia (past the two-week post-stroke milestone) nevertheless remains the single most reliable predictor of aphasia recovery. With respect to lesion site, although it is tied to aphasia type, it generally has more influence on initial severity than on the degree of ultimate recovery (Basso, 1992). Mohr *et al.* (1978) and Brunner *et al.* (1982) have suggested that lesions relegated solely to Broca's area most often create transient and moderate aphasia, whereas lesions to Wernicke's cortex are associated with severe and persistent aphasia. Posterior extent of lesion appears to influence initial severity, and thus long-term outcome, regardless of whether lesion sites are focused in the frontal or temporal–parietal cortex (Basso, 1992). Findings from Ludlow *et al.* (1986) concur, illustrating that of 39 patients with traumatic Broca's aphasia, those whose initial lesions extended farther posteriorly remained aphasic 15 years post-onset while those whose lesions extended more anteriorly had fully recovered. It is tempting to conclude that because posterior extension usually impacts auditory comprehension, recovery of comprehension must lag behind expression. However, the opposite appears to be the case. According to Basso (1992: 345) "... a higher percentage of patients improve in comprehension than production and ... in oral than in written language."

Mesulam (1990) reminds us that Broca's and Wernicke's type aphasias each have associated receptive and expressive deficits. So regardless of aphasia type, we should expect expressive deficits to outlast

deficits in comprehension simply because the active formulation and expression of language is a more complex cognitive exercise than that which is needed for comprehension (Mazzoni *et al.*, 1992). Why, then, should lesions that extend farther into the posterior auditory associative cortex yield initially more severe and ultimately more persistent aphasias than those that extend into the motor cortex?

The answers to this and other questions related to aphasia recovery are not known, but they may ultimately be found in studies of poststroke brain neurophysiology that examines the differential contributions of the dominant and nondominant language cortex (and subcortex) to language recovery. Studies investigating the nature of neural reorganization after stroke and research defining the specific role that speech–language rehabilitation plays in recovery from subacute and chronic aphasia will provide important advances in our understanding of recovery from aphasia.

Recursion

B Clark, Middlesex University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A recursive structure is one in which a constituent dominates another instance of the same syntactic category. Recursion is an important notion in linguistic theory, playing an important role in accounting formally for linguistic creativity. All human languages have recursive properties, and some human thought processes are also recursive. Some linguists claim that recursion is the main defining property that makes human language different from the communication systems of any other species.

In (1) is a small set of recursive rules (the arrow '→' stands for 'can consist of').

(1a) X → Y
(1b) X → X Z

What makes these rules recursive is that X is the output of (1b) and also the input to (1a) and (1b). The rules state that an X can consist of a Y (1a) or an X followed by a Z (1b). These rules characterize any of the sequences in (2).

(2a) Y
(2b) Y Z
(2c) Y Z Z
(2d) Y Z Z Z

In fact, they account for any sequence that contains a Y followed by any number of Zs from zero upward, that is to say an infinite set of sequences. Recursion in human languages is more extensive than this, and so is the creativity of human language.

The creativity of human language can be demonstrated in at least two ways. First, by producing an utterance that it is unlikely that anyone has ever heard before but that speakers of a language will understand, such as (3):

(3) Billy hoped that the runner bean that symbolised the human language faculty hadn't been knocked off the mantelpiece when he adjusted the souvenir from his surfing holiday in Shetland.

Second, by considering specific ways in which sentences seem to be endlessly expandable, illustrated in (4).

(4) Keith said that Billy thought that this was the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

Example (4) involves two distinct recursive processes, each of which provides a means for generating an infinite set of sentences in English. First, we can embed strings within other strings, using verbs that report speech or thought, such as *say* or *think*. We could, for example, create yet another sentence by adding *Sylvia wondered whether* at the front of (4) to give us (5).

(5) Sylvia wondered whether Keith said that Billy thought that this was the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

This process could, of course, be repeated again and again.

Second, we can embed clauses inside noun phrases ('*the book that annoyed…*'). We could expand (4) still further by adding *the chapter that was in* before *the book* to give:

(6) Sylvia wondered whether Keith said that Billy thought that this was the chapter that was in the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

One of the most important insights of Chomsky's approach to linguistics was the observation that language made 'infinite use of finite means' (Chomsky, 1965: 8, quoting von Humboldt, 1836a: 221 and

functional reorganization in the human cerebral cortex after capsular infarction.' *Annals of Neurology 33,* 181–189.

A recursive structure is one in which a constituent dominates another instance of the same syntactic category. Recursion is an important notion in linguistic theory, playing an important role in accounting formally for linguistic creativity. All human languages have recursive properties, and some human thought processes are also recursive. Some linguists claim that recursion is the main defining property that makes human language different from the communication systems of any other species.

In (1) is a small set of recursive rules (the arrow '→' stands for 'can consist of').

(1a) X → Y
(1b) X → X Z

What makes these rules recursive is that X is the output of (1b) and also the input to (1a) and (1b). The rules state that an X can consist of a Y (1a) or an X followed by a Z (1b). These rules characterize any of the sequences in (2).

(2a) Y
(2b) Y Z
(2c) Y Z Z
(2d) Y Z Z Z

In fact, they account for any sequence that contains a Y followed by any number of Zs from zero upward, that is to say an infinite set of sequences. Recursion in human languages is more extensive than this, and so is the creativity of human language.

The creativity of human language can be demonstrated in at least two ways. First, by producing an utterance that it is unlikely that anyone has ever heard before but that speakers of a language will understand, such as (3):

(3) Billy hoped that the runner bean that symbolised the human language faculty hadn't been knocked off the mantelpiece when he adjusted the souvenir from his surfing holiday in Shetland.

Second, by considering specific ways in which sentences seem to be endlessly expandable, illustrated in (4).

(4) Keith said that Billy thought that this was the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

Example (4) involves two distinct recursive processes, each of which provides a means for generating an infinite set of sentences in English. First, we can embed strings within other strings, using verbs that report speech or thought, such as *say* or *think*. We could, for example, create yet another sentence by adding *Sylvia wondered whether* at the front of (4) to give us (5).

(5) Sylvia wondered whether Keith said that Billy thought that this was the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

This process could, of course, be repeated again and again.

Second, we can embed clauses inside noun phrases ('*the book that annoyed…*'). We could expand (4) still further by adding *the chapter that was in* before *the book* to give:

(6) Sylvia wondered whether Keith said that Billy thought that this was the chapter that was in the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

One of the most important insights of Chomsky's approach to linguistics was the observation that language made 'infinite use of finite means' (Chomsky, 1965: 8, quoting von Humboldt, 1836a: 221 and

1836b: 91) and that this fact could be captured in terms of formal rules of grammar that were recursive. A small set of recursive rules for language is illustrated in (7). ('S' stands for 'any sentence', 'NP' stands for 'any noun phrase', 'VP' stands for 'any verb phrase', 'V' stands for 'any verb', 'Art' stands for 'any article', 'N' stands for 'any noun'. The arrow '→' stands for 'can consist of'.)

(7a) S → NP VP
(7b) VP → V NP
(7c) NP → Art N
(7d) VP → V S

Rule (7a) says that a sentence can consist of a noun phrase followed by a verb phrase. Rule (7b) says that a verb phrase can consist of a verb followed by a noun phrase. Rule (7c) says that a noun phrase can consist of an article followed by a noun. Assuming the existence of just the article *the*, the nouns *man* and *woman*, and the verb *saw*, rules (7a), (7b), and (7c) characterize just the four sentences in (8).

(8a) The man saw the man.
(8b) The man saw the woman.
(8c) The woman saw the man.
(8d) The woman saw the woman.

Rule (7d) says that a verb phrase can consist of a verb followed by a sentence. Since a sentence can now contain a verb phrase that itself contains a sentence, our rules now characterize an infinite set of sentences, including (assuming the existence of an extra verb *thought*) those in (9).

(9a) The man thought the woman saw the man.
(9b) The woman thought the man thought the man saw the man.
(9c) The man thought the man thought the man thought the woman saw the man.

The actual rules of the grammar for an actual language will be much more complicated than this, but this is enough to show how a Chomskyan grammar using recursive rules can characterize the grammaticality of an infinite set of sentences. In this way, the rules characterize the fact that language makes 'infinite use of finite means.'

A related, but distinct, notion in linguistics is the notion of 'iteration.' It is sometimes suggested that recursion and iteration are the same thing, but technically they are distinct. An iterative process is illustrated in (10).

(10a) He was very happy
(10b) He was very very happy
(10c) He was very very very happy

Here the word *very* is being repeated for emphasis, but this is not true recursion. One piece of evidence that this is not true recursion is that *very*, which combines only with adjectives or adverbs, cannot be used in a recursive structure with other degree words that combine only with adjectives or adverbs, as in (11). (The asterisk '*' indicates an ungrammatical expression.)

(11a) *too very happy
(11b) *very too happy
(11c) *as very happy
(11d) *very as happy

It is not only human language that is recursive. We can also entertain thoughts that contain other thoughts. I might think, for example, that you think that I think that Fred thinks. . .and so on. Work with primates (Tomasello and Hare, 2003) has suggested that they can represent recursive thoughts, but only to a limited degree. So it is possible that our ability to handle recursion is one thing that marks us as different from other species and that this was significant in the development of human language. Perhaps Hauser *et al.* (2002) have taken the strongest view on this, suggesting that recursion is the one key defining feature of language seen as a mental faculty.

Reductionism

S Chapman, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

In philosophy, the term 'reductive' is applied to any attempt to explain a complex phenomenon entirely in terms of simpler, or more clearly understood, phenomena. Reductionism is therefore the doctrine that explanations should involve, or be reduced to, the simplest and the fewest elements possible. Proponents of reductive theories claim that they allow systematic explanations of theoretically problematic entities. Opponents argue that, by concentrating on selective aspects of a complex phenomenon, reductionism can result in unjustified oversimplifications in comparison to more holistic approaches.

Within the philosophy of language, there have been various attempts to explain meaning in terms of other, arguably more theoretically tractable, systems. Accounts of linguistic meaning in terms of logic, for example, could be described as reductive. These include the logical notation proposed by Gottlob Frege, the verificationism of the Vienna Circle, and the truth theories elaborated by Alfred Tarski and Donald Davidson.

One of the major debates in mid-20th-century linguistics, Noam Chomsky's response to behaviorism, centered on a particular type of reductionism. Behaviorism draws on a reductive theory of mind, in that it explains apparently complex mental phenomena with reference only to behavior established by reinforced responses. In his 1957 book *Verbal Behavior,* B. F. Skinner argued that the acquisition and use of language could be explained in terms of conditioned behavior. In his review of this book, Chomsky argued that it was only by vastly oversimplifying the facts of language that Skinner was able to exclude any reference to mental phenomena; when the true nature of language, including creativity, was taken into account, it was clear that it could not be reduced to the observable behavior of speakers.

Reductive impulses can, however, be traced in Chomsky's own account of language. Concentrating on language as a mental phenomenon, Chomsky explains it as an innate faculty, an inherent part of human nature, and therefore ultimately a matter of biology. Criticism has been voiced, for instance within the movement of 'integrational linguistics,' of this attempt to reduce the linguistic to the biological. Chomsky's insistence that the mental structure of language is the only legitimate focus of linguistic study has further been dismissed as an attempt to reduce the intricacy of human communication to a narrowly grammatical system. Chomsky's defenders argue that his theories do not attempt to explain all of human communication, a prohibitively complex undertaking, but only the core linguistic component of it.

Reductive approaches are to be found throughout present-day linguistics, and indeed the general ambition within many branches of linguistic theory is to explain complex sets of facts by means of a restricted number of entities and methods of combination. For instance, phonology explains the diversity of speech sounds of a particular language by means of a limited number of phonemes. Syntax explains the infinite possibility of sentences for any language in terms of a finite set of words and grammatical rules. Indeed, it could be argued that at least some degree of reductionism is an inevitable precondition for any explanatorily successful theory.

Reduplication

S Inkelas, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Reduplication is a morphological word formation process in which some portion of a word is doubled. Total reduplication doubles the entire word or stem, as in Indonesian noun pluralization (e.g., *buku* 'book,' *buku-buku* 'books'; Cohn, 1989); partial reduplication doubles some phonologically characterized subpart of the word or stem, as in Agta (Central Cagayan) noun pluralization (e.g., *takki* 'leg,' *tak-takki* 'legs'; Marantz, 1982).

Reduplication is often semantically iconic, conferring, for example, plurality on nouns; intensity or attentuation on adjectives; and pluractionality, iterativity, progressivity, intensity, or attenuation on verbs. Reduplication (especially when partial) can also be found with less iconic and quite diverse semantic or morphological functions, including noun-to-verb derivation, verb-to-noun derivation, intransitivization, subject agreement, and possessive marking. Works surveying crosslinguistic reduplicative semantics include Moravcsik (1978), Kiyomi (1993), Regier (1994), and Niepokuj (1997).

Reduplication has attracted the greatest attention in the theoretical literature for the light it sheds on morphology, phonology, and their interface. Most discussion focuses on partial reduplication, which varies widely both within and across languages.

Morphology

Reduplication can be the sole marker of a morphological category, as in Indonesian and Agta noun pluralization, or it can be a required concomitant of particular affixes. In Roviana, for example, the derivation of instrumental or locational nouns from verbs is marked simultaneously by reduplication and the suffix *-ana*; thus *ha^{m}bo* 'sit' nominalizes as *ha^{m}bo-ha^{m}botu-ana* 'chair' (Corston-Oliver, 2002: 469). The reduplication co-occurring with *-ana* serves no distinct semantic function of its own.

The literature offers several points of view as to whether reduplication should be classified morphologically as affixation or compounding. Many researchers have adopted the proposal by Marantz (1982) that all reduplication, whether partial or total, is the affixation of a phonologically skeletal morpheme. Lacking a segmental substance of its own, the reduplicative skeleton is fleshed out by copying the segmental content of the base of affixation and associating the copied segments to the reduplicative skeleton (see Figure 1). For total reduplication, Marantz

Figure 1 Reduplication as the affixation of a phonologically skeletal morpheme.

proposes the affixation of a segmentally empty morpheme that can accommodate all of the copied segments, regardless of number; subsequent work by McCarthy and Prince (1986) suggests instead the affixation of a prosodic word constituent (see later discussion).

An alternative view sees reduplication not as phonological copying, driven by a skeletal affix, but as morphological doubling, namely the requirement that a given morphological subconstituent occur twice in the same word; the difference between total and partial reduplication lies in whether or not one of these copies is phonologically truncated. As morphological doubling, reduplication is more structurally similar to compounding than to affixation; it is a subtype of compounding in which the two members must mean the same thing. In support of this view, Inkelas and Zoll (2005) cite cases of synonym compounding and 'divergent allomorphy,' in which the two copies can differ in their morphological and phonological makeup as long as their meanings are identical. In Ndebele verb stem reduplication, for example,

lim-il-e
'cultivate for/with (subjunctive)'

lim-a-lim-il-e
'cultivate for/with (subjunctive), here and there'

the stem *lim-il-e* reduplicates as *lim-a* + *lim-il-e*, where the *-a* appearing in the first copy is a semantically empty suffix that is used elsewhere in the language but is not present in *lim-il-e* (Sibanda, 2004).

Recent work in Optimality Theory has appealed to both the affixation and compounding analyses of reduplication; Generalized Template Theory holds that some cases of partial reduplication should be viewed as affixation, whereas reduplication, as well as some types of partial reduplication, should be viewed as compounding (McCarthy and Prince, 1994; Urbanczyk, 1996).

Phonological Shape of Partial Reduplicants

In a seminal article, Moravcsik (1978) observed that partial reduplication does not, in general, seem to duplicate some existing phonological constituent

(e.g., syllable) of the base, regardless of its segmental makeup. Rather, partial reduplicants tend to have their own invariant overall shape. The typology of possible shapes has been a major topic of discussion in the literature. McCarthy and Prince (1986) contributed the observation that the range of possible reduplicant shapes mirrors the range of patterns that are found in truncation: Both reduplicative and non-reduplicative truncation make use of the constituents in the prosodic hierarchy, namely mora, syllable, foot, and prosodic word. Total reduplication requires only that the reduplicant be a prosodic word, with no upper limit on its size. Partial reduplication occurs when the reduplicant is required to be a mora, syllable, or foot, and the base happens to be long.

A recent topic of discussion in the literature has been the duplication of single segments (e.g., Hendricks, 1999). In Spokane, for example, the repetitive infix *-e-* occurs inside a word-initial consonant cluster, for example, /*e-* + *šl'n'tén'*/ → *š-e-l'n'tén'* 'I cut it up repeatedly'; when the word begins with a CV sequence, however, the infix is prefixed, and the word-initial consonant is copied to its left, for example, /*e-* + *n'íč'n'tx*^{w}/ → *n'*-e-*n'íč'n'tx*^{w} 'you kept cutting' (Bates and Carlson, 1998: 655). Single-segment copying differs in at least two ways from more canonical reduplication patterns: (1) It does not involve a constituent of the prosodic hierarchy, (2) it has no parallel in truncation, and (3) it is typically motivated on purely phonological grounds rather than realizing a morphological category. For these reasons, it has been suggested that single-segment duplication should be considered a phonological operation, whereas reduplication is a morphological process (Yu, 2003; Inkelas and Zoll, 2005).

Phonological Reduction in Reduplicants

A second major phonological generalization about partial reduplicants is that they are often structurally reduced. In an influential crosslinguistic survey, Steriade (1988) found that partial reduplicants often reduce vowel length contrasts, simplify consonant clusters, or collapse quality distinctions among vowels or consonants. For example, initial syllable reduplication simplifies consonant clusters in Sanskrit (*krand* → *kan-i-krand* 'cry out'; Steriade, 1988) and Tagalog (*ka-trabaho* → *ka-ta-trabaho* 'just finished working'; McCarthy and Prince, 1986). Steriade's finding that partial reduplicants are often structurally unmarked relative to their bases underlies the Base-Reduplication Correspondence Theory (BRCT) approach to reduplication developed within Optimality Theory by McCarthy and Prince (1995). In BRCT, the phonological correspondence between the reduplicant and base (FAITH$_{BR}$) not only provides the reduplicant with phonological substance but also actively enforces surface phonological identity between the copies. If FAITH$_{BR}$ is top-ranked, the reduplicant and base will not differ; if a markedness constraint is ranked above FAITH$_{BR}$, the reduplicant will be phonologically unmarked relative to the base. The consonant cluster reduction in Sanskrit and Tagalog reduplicants would follow, on this approach, from the ranking *COMPLEX-ONSET » MAX-C$_{BR}$.

Markedness reduction of this kind appears to be specific to partial reduplication; it is virtually unknown in total reduplication, with the exception of tone, which often fails to reduplicate (Downing, 2005).

Fixed Segmentism in Reduplication

Although rarely, if ever, reduced in overall markedness, total reduplication is often subject to the kind of fixed segmentism termed Melodic Overwriting (McCarthy and Prince, 1986), in which part of the copy is supplanted by a fixed segmental string. In Kolami echo reduplication, for example, the initial portion of the first syllable of the second copy is replaced by *gi*, for example, *kota* → *kota-gita* 'bring it if you want to' (Emeneau, 1955). Melodic Overwriting is an extreme case of affixation accompanied by reduplication, as previously mentioned, the difference being that in Melodic Overwriting, the affix competes with the reduplicant for surface position. Although the superimposed material is usually at one edge, it can also be medial; in Amele irregular iterative reduplication, for example, all vowels in the copy are replaced: *bala-doʔ* → *bala-bulu-doʔ* 'to tear and scatter', *ʔaʔagan-eʔ* → *ʔaʔagan-ʔuʔugun-eʔ* 'to talk sporadically in sleep' (Roberts, 1991). Siroi adjective pluralization exhibits replacement of a medial consonant with /g/, which has the further unusual property of occurring in both copies: *maye* → *mage-mage* 'good (pl.)' (Wells, 1979). Melodic Overwriting is more common in total reduplication than in partial reduplication.

Phonological Opacity in Reduplication

The phonological aspect of reduplication that has been the focus of the most intense discussion in recent years is opacity. Although phonologically opaque alternations are known to occur outside of reduplication as well, they have attracted special attention in reduplication, perhaps because they are especially prevalent there; the terms 'underapplication' and 'overapplication' are generally used only for reduplicative opacity. Most instances of reduplicative opacity occur in partial reduplication.

In Javanese, for example, /a/ raises to [ɔ] when word-final (Horne, 1961: 70). Raising is not expected in forms such as *medja-medja-ku* 'my tables,' in which an /a/-final stem is both reduplicated and suffixed because neither /a/ is word-final. When reduplication occurs without suffixation, however, raising occurs in both copies: *medjɔ̯-medjɔ* 'tables.' Raising is transparent in the second, word-final, copy but overapplies, opaquely, in the first.

One popular take on reduplicative opacity is that it results from the pressure for the reduplicant and base to be phonologically identical on the surface (Wilbur, 1973); this pressure can foil the transparent application of phonological alternations that might otherwise disrupt base-reduplicant identity. Wilbur's identity principle underlies McCarthy and Prince's BRCT theory.

Kiparsky (2000) took a broader view, attributing opacity within and outside reduplication to stratal interleaving, not to a reduplication-specific identity imperative. According to Kiparsky, opacity results when the phonology of one morphological stratum (e.g., word-level) obscures the phonology of an earlier stratum (e.g., stem-level). This effect is easily seen in cases such as Chamorro, in which final-CV reduplication (*buníta* → *buníta-ta* 'very pretty'; *mági* → *mági-gi* 'nearest') obscures an otherwise very regular pattern of stem-penultimate stress (e.g., *karéta* 'car,' *karetá-hu* 'my car') (Topping, 1973). In a model such as Kiparsky's, Chamorro reduplication is a word-level process, whereas penultimate stress assignment is stem-level.

What Is Reference?

Reference is the relation that obtains between a use of a linguistic expression and what it stands for or denotes. Philosophical theories of reference aim to explain this relation. They address questions such as: Can we specify necessary or sufficient conditions for a use of an expression to single out some particular referent? What makes it the case that a sequence of marks or noises refers to what it does? What grounds the conventional word-referent relations that we take for granted in the unreflective course of linguistic communication?

Reference is a fundamental concept within the subdiscipline of philosophical inquiry that studies language and thought. It is intimately tied to some other core concepts, such as meaning, truth, and representation, and it lies at the root of various general philosophical issues. To cite a few illustrative examples (some of which are discussed later): [1] there is a venerable tradition of using data about referring expressions to support metaphysical and epistemological conclusions about their referents, running at least from Aristotle's *Categories* through to many influential 20th-century works; [2] the ancient problem of nonbeing – cf. Plato's *Parmenides* for a classic discussion, and Lewis (1986) for discussion of some contemporary variants – is in part a problem about reference to nonactual, or nonconcrete, objects; [3] reference plays a central role in some of the most provocative and broad-ranging recent work in philosophy, including in particular the varieties of externalist arguments spurred by Kripke (1972) and Putnam (1975).

Proper names take center stage in debates about reference, as names are explicitly introduced to refer to specific individuals. Other much-discussed, basic cases of reference include uses of demonstratives (such as 'that duck') and indexical pronouns ('she') to refer to individuals which the speaker currently has in mind. Beyond these paradigm cases, though, there is not much uncontested ground. For example, there are long-standing debates over whether definite descriptions – expressions of the form 'the F' – should be classified as referring expressions (for discussion, *see* **Descriptions, Definite and Indefinite: Philosophical Aspects**).

In addition to such differences of opinion, there also are significant differences of usage. In its strictest sense, 'reference' applies only to the relation between singular terms (such as names and pronouns) and what they are used to single out. On this usage, 'reference' names the simplest sort of word-object relation; and whatever the semantic relations are, precisely, that are involved in, say, general terms ('justice') or predicates ('is tall'), they are distinct from reference. In a broader sense of the term 'reference,' any expression that makes a difference to the truth-conditions of sentences in which it occurs thereby has a referent – general terms refer to universals, predicates refer to properties, and so on. So, in the former, strict sense of the term, the theory of reference is more or less co-extensive with the study of the semantics of singular terms, whereas, in the latter, broad sense, the business of the theory of reference is to assign semantic values to all independently meaningful expressions.

There also are differing views as to whether the term 'reference' just applies to language-world relations, or whether mental phenomena, such as concepts, also should be said to refer. On the one hand, some treat 'reference' as a two-place relation between a representation and what it represents, and so take the term to apply in kind to (at least) word-world and concept-world relations. In this inclusive sense, all thought or talk about something in particular involves reference to it. On the other hand, there are those who hold that there are important differences between referring to something and thinking of it, and so restrict to the term 'reference' to language-world relations. Their point is not so much to deny that the problems of word-reference and of concept-reference are intimately related – that is true on virtually any approach to the relation between language and thought. Rather, their point is that referring is something that speakers do in the course of performing speech acts, not something that words themselves do. These theorists hold that the fundamental notion in the theory of reference is *speaker's reference* – an irreducibly four-place relation involving a speaker, an expression, an audience, and a context.

For comprehensiveness, I will use the term 'reference' in a fairly broad, inclusive sense. For brevity, I will concentrate on uses of words, and I will treat reference as a two-place relation between a use of a word and its referent. Given these preliminaries and assumptions, the central problem for a theory of reference is to come up with a true, informative account of what the 'R' stands for in the schema:

[Ref] 'X' refers to Y if 'X' stands in relation R to Y

Descriptivism

Descriptivist Theories of Reference

Even though philosophical problems that turn on the notion of reference are more or less as old as philosophy, the development of theories of reference – of explicit attempts to articulate how it is that terms reach out to their referents – does not occur until the seminal semantic work of Frege and Russell. (Some might argue that the idea theorists of the early Modern period had a theory of reference – *see* **Ideational Theories of Meaning** for discussion.) Down different avenues, Frege and Russell both defend descriptivist views about reference, and their views dominated the scene for most of the 20th century.

Descriptivists take the definite description ('the tallest woman in Mongolia', 'the millionth car to roll off this assembly line') as the paradigm for understanding the word-object referential link. The relation between descriptions and their referents is relatively straightforward: the term expresses an identifying condition, and designates whatever (if anything) uniquely satisfies that condition. In its most general sense, 'descriptivism' names the view that this is how reference works, that words refer to specific things by expressing an identifying condition which singles out the referent. For starters, then, let us characterize the core tenet of a descriptivist theory of reference as follows:

> [D] 'X' refers to Y if Y satisfies the descriptive condition expressed by 'X'

There are more specific variants of descriptivism, which just apply to a distinctive category of terms, as opposed to making claims about reference in general. (For example, Lewis (1970) develops a descriptivist approach to theoretical terms.) The most common usage of 'descriptivism,' though, specifically designates an approach to ordinary proper names. According to this view, names such as 'Aristotle' or 'Romania' hook onto and express information about something in particular, akin to descriptions, by expressing a uniquely identifying condition and designating whatever satisfies the condition. This approach to ordinary proper names is the kernel in common among Frege's and Russell's otherwise rather divergent views about reference.

Frege's and Russell's Versions of Descriptivism

In their earliest work, Frege and Russell both espoused referentialist views of meaning, according to which the meaning of an expression is whatever it is to which the expression refers. However, they came to believe that referentialism must be rejected or modified, because two terms can have the same referent but differ in meaning.

Frege's signature example concerns the names 'Hesperus' and 'Phosphorus.' According to the lore, the Evening Star (the brightest heavenly body in the evening sky at certain times of the year) was baptized 'Hesperus,' whereas the Morning Star (the brightest body in the dawn sky at certain times) was baptized 'Phosphorus'. With the growth of astronomical knowledge, it turns out that Hesperus *is* Phosphorus, and that is not a star at all but the planet Venus. Frege and Russell agree that pairs of sentences such as the following differ in meaning:

1a. Hesperus is Hesperus.
1b. Hesperus is Phosphorus.
2a. The ancient Babylonians believed that Hesperus is visible in the evening.
2b. The ancient Babylonians believed that Phosphorus is visible in the evening.

However, because these sentences are constructed from co-referential parts, the referentialist view is committed to treating them as synonymous.

Frege (1892) concludes that, in general, the meaning of a term is not just its referent. Instead, every significant linguistic expression is associated with a sense that determines its referent. The sense specifies the condition that must be met in order to be the referent, which clearly differ for the cases of 'Hesperus' and 'Phosphorus.' Co-referential expressions can have distinct senses, and expressions need not have an actual concrete referent to have a sense. Thus, on Frege's view:

> [D, Frege] 'X' refers to Y if Y satisfies the sense 'X' expresses

This type of view is called 'mediated' or 'indirect' reference. The link between word and referent is *indirect* because there is something *mediating* the word-referent link. On this approach, any referential relation involves three terms: [1] a sign or symbol, [2] its sense, and [3] the referent picked out by the sense. (Note that there may be no actual entity to serve as term [3] – as in the case of, say, 'Santa Claus' or 'Pegasus.' However, such cases still fit with the general picture, as the names express a sense that specifies the condition that must be met to count as the referent.) (*see* **Sense and Reference: Philosophical Aspects** for more on Frege's view.)

Russell rejects Frege's views, arguing that the postulation of intermediaries between word and referent creates rather than solves problems. Russell's view is premised on a firm distinction between the following two sorts of term: "(1) a *name*, which is a simple symbol, directly designating an individual which is

its meaning, and having this meaning ... independently of all other words; (2) a *description*, which consists of several words, whose meanings are already fixed, and from which results whatever is to be taken as the 'meaning' of the description" (1919: 283). (Following Russell [1918], I'll call the former 'logically proper names.') Concerning logically proper names, Russell is a direct reference theorist, an unrepentant referentialist. Reference is *direct* in that there is no third term mediating the word-referent relation. The meaning of a logically proper name is its referent.

However, for the reasons illustrated by (1a–b) and (2a–b) above, Russell argues that ordinary proper names (such as 'Hesperus' or 'Aristotle') belong in the category of descriptions, not of logically proper names. He holds that it is not possible for co-referential logically proper names to differ in meaning – "For the name itself is merely a means of pointing to the thing ... so that if one thing has two names, you make exactly the same assertion whichever of the two names you use ..." (1918: 245). In contrast, descriptions (such as 'the inventor of bifocals' and 'the first Postmaster General of the US') can differ in meaning while describing the same referent. Russell concludes that, since ordinary proper names are subject to the phenomena illustrated by (1a–b) and (2a–b), they are really just disguised or abbreviated descriptions – "Common words, even proper names, are usually really descriptions" (1911: 253). Thus, Russell also espouses a form of descriptivism:

> [D, Russell] For any ordinary proper name 'N', 'N' refers to Y if Y satisfies the description 'the F' which the speaker has in mind in uttering 'N'

Differences Between Descriptivist Views

Despite the fact that Frege and Russell both espouse descriptivist accounts of ordinary names, their approaches to reference are quite far apart. On Russell's direct reference view, there must be some primitive cases in which it is impossible to have sameness of referent but distinctness of meaning. He holds that we must be directly acquainted, and not just indirectly linked via descriptions, with the referents of some of our terms. (Otherwise "... we get the conclusion that we know nothing at all about ..." the referents of our terms, as Russell puts the point in a letter to Frege [reprinted in Frege (1980: 169)].) So, apart from, and more fundamental than, his views about ordinary names, Russell espouses an acquaintance-based theory of reference:

> [A] 'X' refers to Y if Y is the entity with which the speaker is acquainted that the speaker intends to single out by uttering 'X'

(It is crucial to Russell's view that acquaintance is *immediate*, in that for any co-referential pair 'X'-'X*,' one cannot be acquainted with their referent and yet judge that X is distinct from X*.) Russell holds that one can only use a logically proper name to refer to something to which one is directly acquainted (1918: 201). Furthermore, even in the case of a description, one can only understand a description if one is acquainted with the meanings of the terms of which it is composed (1911: *passim*) – i.e., to understand the term 'the tallest woman in the room', one must be acquainted with the meanings of 'tallest,' 'woman,' 'room,' and so on.

According to Russell, one needs to fall back on something like [A] in order to address questions that are subsequent to, and more fundamental than, a commitment to some version of [D]. In effect, [D, Russell] reduces the ordinary-naming-relation to the description-relation; but still, according to Russell, we do not yet have a theory of reference. In order to explain how 'the tallest woman in the room' expresses the specific identifying condition that it does, one needs an account of the referents of its primitive parts – i.e., a theory of reference for 'tallest,' 'woman,' and so on. Furthermore, this account had better not just appeal to more descriptions, or else we are not getting anywhere. So, Russell holds that [D] needs to be supplemented, if we are to have an account of how our utterances get hooked up to particular referents.

This problem never seems to have bothered Frege; and yet it is not clear whether this is an oversight. (Perhaps Frege's senses are relevantly different from Russell's descriptions; perhaps the moral is that a direct-reference-descriptivism needs to be supplemented by something like [A], whereas an indirect-reference-descriptivism does not.) In any case, it can be argued that [D] is not yet a theory of reference, because it presupposes, rather than explains or grounds, reference. To help oneself to some specific Y as that which satisfies the descriptive condition expressed by 'X,' so this Russellian allegation goes, is to beg the very question that a theory of reference ought to answer.

No such worry applies to [A]. Acquaintance is a clear and distinct answer to the fundamental question of reference. However, it puts rather tight constraints on reference. By 1918, Russell's insistence that one must be immediately acquainted with something in order to refer to it lead him to the view that only 'this', used to refer to current sense impressions, qualifies as a referring expression. Subsequent theorists have found this unacceptable, and so reject Russell's tight restrictions on reference.

For decades, work in the theory of reference consisted largely of the development of other variants of

descriptivism (cf. Searle [1958]; Strawson [1959]). However, some deep criticisms of descriptivism emerged in the 1970s, which lead to another major wave of original work in the theory of reference.

Antidescriptivism and the Causal-Historical Theory of Reference

Problems With Descriptivism

Kripke (1972) is the most thorough and influential critic of descriptivism, whereas Donnellan (1970), Putnam (1975), and Kaplan (1977) also develop important criticisms. Three widely discussed problems with descriptivist theories of names are known as the modal problem, the epistemic problem, and the semantic problem.

To illustrate the modal problem, take any proper name (say, 'Aristotle') along with descriptions that are true of its referent ('the most famous of Plato's students,' or 'the teacher of Alexander'). Consider the differences in truth-conditions of the following:

1. Aristotle had brown hair.
2. The most famous of Plato's students had brown hair.

Even if (1)–(2) actually agree in truth-value, they need not have. Had things gone differently (and, say, Aristotle died young, or went into commerce), then the truth-values of (1)–(2) could vary independently – i.e., each might have been true while the other is false. A similar contrast could be drawn using virtually any name-description pair, and many take this phenomenon to indicate a deep difference between names and descriptions.

To illustrate the epistemic problem, if 'Aristotle' meant something like 'Plato's most famous student,' then the following would be self-evident to anyone who understands it:

3. Aristotle is Plato's most famous student.

This consequence is false, as (3) is not at all trivial or self-evident. Again the point generalizes, having nothing to do with this specific example; and the putative upshot is that names like 'Aristotle' are not equivalent in meaning to any particular descriptions.

The semantic problem is that speakers may be competent to use a name even if the descriptive conditions they associate with the name does not suffice to single out the referent. That is, one might just think that 'Aristotle' names some famous Greek guy (or perhaps even confuse Aristotle with Heraclitus), but yet nonetheless one could still refer to Aristotle by uttering 'Aristotle'. Again, the conclusion seems to be that there are important differences between reference by name and the satisfaction of descriptive conditions. (*see* **Proper Names: Philosophical Aspects** for discussion.)

Collectively, these three problems are widely thought to spell the end for descriptivist accounts of names. (This is not unanimous, however – cf. Searle [1983] and Bach [1987] for descriptivist replies.) Kripke (1972) and Putnam (1975) develop similar problems for some varieties of general terms. Still other, related problems for descriptivism are raised by indexicals – even if satisfactory descriptivist accounts could be given for some terms, it is not plausible to hold that all reference is descriptive, as is shown by cases like 'It is quiet here now' (cf. Kaplan [1977]).

The Causal-Historical Theory of Reference

The critics of descriptivism put forth a different picture of reference, knows as the causal-historical theory. Originally, the theory is only developed for proper names (cf. Donnellan [1970]; Kripke [1972]) and natural kind terms (cf. Kripke [1972]; Putnam [1975]). However, there have been attempts to fashion more general, comprehensive views of reference along these lines (for discussion, see Stalnaker [1997]; Devitt and Sterenly [1999]).

The crux of this picture is that certain expressions refer to certain things in virtue of a causal-historical relation between word and object, initially fixed during a dubbing or baptism and propagated from there to subsequent speakers, who implicitly defer to that initial dubbing in using the expression to refer. The view has it that descriptivists are wrong to demand that, in order to significantly use a term, speakers are required to have an identifying description of its referent. Rather, once a word-referent convention is in place, all that is required in order to use the term to refer is a deferential intention to comply with the convention – i.e., the (implicit) intention to use 'X' to refer to what others have used 'X' to refer to. On this approach, reference depends not simply on what the speaker thinks, but also on certain factors external to the speaker's head, factors pertaining to the speaker's linguistic community and to the environment in which the expression in question evolved. The basic idea is:

> [CHT] 'X' refers to Y if 'X' stands in the right sort of causal-historical relation to Y

(*see* **Causal Theories of Reference and Meaning** for more detail).

Many of Russell's successors have worked to loosen the tight restrictions on his notion of reference, by replacing acquaintance with something more broadly applicable and accessible. The [CHT] is a

significant step forward in this direction. It is an externalist theory of reference. Internalist views of reference hold that reference is fully determined by the intrinsic content of the speaker's head; externalists deny this. Externalists hold that two speakers could be in the same mental state and utter the same sounds, but nonetheless their utterances have different referents – because of differences in the histories of how the words reached them, or of differences in the environments to which they are causally connected. (For discussion, *see* **Externalism about Content**.)

Intuitively, reference is a relation involving (at least) a speaker, an expression, and a referent; externalists hold that it is a mistake to think that the nature of this relation could be fully characterized by analyzing only one term of this relation (i.e., the intrinsic content of the speaker's head). Most theorists who articulated views about reference prior to the [CHT] (including Frege and Russell) are commonly characterized as internalists. In the wake of the [CHT], though, externalism about reference has become the norm. Most subsequent theorists agree that the [CHT] makes a progressive step forward, in giving some of the weight in determining reference to the extrinsic relations in which speakers stand to other speakers and to their environments.

The [CHT] led to a resurgence of interest in the notion of direct reference. Many take the arguments against descriptivism to apply to all indirect reference theories, and so to make it plausible that the meaning of a term is just its referent. In addition, many see a complementary fit between the causal-historical chain of transmission story about reference and the direct reference approach to the question of meaning or content. (*see* **Proper Names: Philosophical Aspects** for discussion.)

Problems With the Causal-Historical Theory

There are many problems with the causal-historical theory of reference. For instance, Evans (1973) points out that some words have in fact changed their referents over time, even despite the deferential intention to preserve the convention in question, and argues that the [CHT] cannot account for this phenomenon. For another example, Searle (1983: 249) offers as a *reductio* of the theory the putative consequence that his utterances of 'Aristotle' might refer to a barstool in Hoboken "if that is what the causal chain happened to lead to." To cope with these and other problems, many have sought to defend hybrid views, which aim to combine the strengths while avoiding the weaknesses of [D] and [CHT] (cf. Evans [1973, 1982]).

More generally, though, the [CHT] leaves important questions unaddressed. One problem concerns specifying exactly what should count as 'the right sort of causal-historical relation'. As Stalnaker (1997: 543) puts it: "Causal connections are ubiquitous . . . there are a great many individuals causally implicated in [any] use of [any] name. . . . . A proper causal theory of reference would have to specify just what sort of causal connection is necessary and sufficient for reference, and that is a notoriously difficult demand." Kripke (1972: 96) is explicit that he is not offering a reductive analysis of reference: "When the name is 'passed from link to link', the receiver of the name must, I think, intend to use it with the same reference as the man from whom he heard it, . . . [T]he preceding account hardly *eliminates* the notion of reference; on the contrary, it takes the notion of intending to use the same reference as a given." (Cf. Kaplan's [1990] discussion of the point that the intention to preserve reference is not itself a causal notion.) Here we see why the [CHT] is open to the allegation that it begs the key question in the theory of reference, by helping itself to successful reference. Critics allege that it boils down to the relatively toothless claim that: 'X' refers to Y if everyone else has used 'X' to refer to Y.

Of course, the [CHT]'s developers recognize the need for a separate story about what determines reference in the first link in a causal-historical chain of transmission. However, their remarks about baptisms or dubbings fall far short of a comprehensive account. (Cf. Devitt and Sterenly's [1999] discussions of the 'qua'-problem for a sense of some of the relevant unfinished business.) So, while most agree that the [CHT] provides a better picture than [D], it has yet to be fleshed out into a specific, comprehensive theory of reference.

Skepticism, Naturalism, and Minimalism About Reference

Some influential thinkers are skeptical about the prospects of coming up with a satisfactory theory of reference. Chomsky (1993), for instance, argues that the debates about reference are hopelessly flawed because they presuppose an implausible, unscientific conception of language. The precise import of Chomsky's complaints is unclear, though. In particular, and explicitly, they do not apply to the relatively concrete and tractable notion of speaker's reference (i.e., a four-place relation between speaker, expression, audience, and context).

Quine (1960) is perhaps the most influential skeptic about reference, arguing that there are no determinate facts about reference, no objective thing to be

gotten right. Quine takes this conclusion (which he calls the 'inscrutability of reference') to be an instance of the general point that theories are underdetermined by evidence – i.e., for any finite set of data, there are an infinite number of distinct theories that are consistent with, and could purport to explain, the data. In the case of reference, the claim is that, for any finite set of evidence about a given speaker, there are a number of distinct word-referent assignments that are compatible with it. (To take one of Quine's central examples, no data will tell us whether a given speaker is using 'rabbit' to refer to rabbits, to time-slices of rabbits, to undetached rabbit parts, and so on.) There is no principled way of deciding between these competing assignments; and hence, there is no determinate fact of the matter as to what words are used to refer to. From here, Quine draws pessimistic conclusions about the scientific credentials of such notions as reference.

Many aspects of Quine's approach have been criticized. Still, much subsequent work on reference is addressed to Quine's underlying challenge of explaining reference within the ontology and methodology of the natural sciences. This is known as the demand for a naturalistic theory of reference, and a number of candidates were proposed in recent decades.

One such candidate is another causal theory of reference – also called the 'information-theoretic' approach (cf. Stampe [1977]; Dretske [1981]; Fodor [1990]). The general idea is that information is a species causal co-variance, that for a word 'X' to mean something Y is for tokens of 'X' to reliably indicate Y. As applied to reference, the view comes to something like:

[CT] 'X' refers to Y if Y tends to cause or bring about tokens of 'X'

However, in addition to inheriting some of the general worries about [CHT], [CT] is subject to counterexamples. For almost any word-referent pair 'X'–Y, it is not difficult to find conditions in which things distinct from Y tend to cause 'X's, and conditions in which Y does not tend to cause 'X's. Despite ingenious work to patch things up, the consensus seems to be that this type of causal theory can only succeed in delivering an account of reference that accommodates our intuitions about the normativity and determinacy of reference by smuggling in intentional, semantic notions, and thus by helping itself to reference and forgoing naturalism. (For discussion see Loewer (1997), and **Causal Theories of Reference and Meaning**.)

Another naturalistic approach to reference is the teleological theory, whose most thorough proponent is Millikan (1984). The idea here is that:

[T] 'X' refers to Y if it is the function of 'X's to indicate Y

Here 'function' is a familiar notion from evolutionary biology – roughly, X's function is what X does, that explains why X exists. However, this theory, too, has serious troubles accounting for the normativity and determinacy of reference (cf. Fodor [1990]; Loewer [1997]). Although teleological considerations afford a compelling story about why agents like us have developed the capacity to refer, it is a long way from there to specifying necessary or sufficient conditions for determining the referent of a given use of a word.

Another reaction to this long and sordid history is the minimalist (or 'deflationary') approach (cf. Horwich [1998]; Field [2001]). Minimalists hold that reference is simple, not reducible to anything more fundamental. (Minimalism about reference is often conjoined with minimalism about truth – *see* **Truth: Theories of in Philosophy** for discussion.) Our meaning what we do by 'refers' consists entirely in our inclination to accept disquotational schemas – 'Aristotle' refers to Aristotle, 'Romania' refers to Romania, and so on – and there is nothing else to be said, by way of necessary or sufficient conditions. Rather, all that should be said is something like:

[M] 'X' refers to X

[M] is of course no definition: reference is not reduced to, or explained in terms of, anything more basic. However, one conclusion that is fairly well supported by the failed attempts to define reference is that such a reductive analysis may well be unattainable. To some extent, it is a matter of taste whether one classifies minimalist views as theories of reference or as a variety of skepticism about reference.

Even if there is something right about the minimalist approach, though, [M] hardly seems to illuminate the content of the concept 'reference.' Furthermore, there are specific objections to minimalism (cf. Loar [1995]; Loewer [forthcoming]). For example, it is not clear that there could be a satisfactory minimalist account of indexical expressions. (That is, the disquotational line on 'Aristotle' and 'Romania' does not carry over smoothly to 'I' or 'here.') Because these are core, basic cases of reference, this might point to something deeply suspect about minimalist views.

Summary

The fundamental problem in the theory of reference (given our preliminary assumptions) is to come up with a true, informative account of what the 'R' stands for in the schema:

[Ref] 'X' refers to Y if 'X' stands in relation R to Y

Work in the theory of reference largely consists of disputes between two camps, descriptivists and causal-historical theorists:

[D] 'X' refers to Y if Y satisfies the descriptive condition expressed by 'X'

[CHT] 'X' refers to Y if 'X' stands in the right sort of causal-historical relation to Y

Descriptivists tend to be internalists, and descriptive reference is mediated or indirect, whereas the causal-historical theory is externalist and more friendly to direct reference. As we have seen, though, whereas [D] and [CHT] are major players in the semantics of proper names, both are – albeit from different directions – open to the allegation that they presuppose rather than explain or ground reference.

Bracketing off reference via descriptive conditions and reference via deference to causal-historical chains (as well as the hybrid views), there are at least four other basic answers to the fundamental question of reference (respectively, acquaintance, causation, teleology, and minimalism):

[A] 'X' refers to Y if Y is the entity with which the speaker is acquainted that the speaker intends to single out by uttering 'X'

[CT] 'X' refers to Y if Y tends to cause or bring about tokens of 'X'

[T] 'X' refers to Y if it is the function of 'X's to indicate Y

[M] 'X' refers to X

The problem with Russell's version of [A] is that it is incompatible with the platitude that reference is a tool used in the intersubjective communication of information – i.e., acquaintance is a private subjective affair, but reference is not. However, there is a recent resurgence of interest in the notion of acquaintance, and it promises to avoid some of these problems. [CT] and [T] have certainly not been ruled out, but counterexamples have yet to be satisfactorily addressed. (Note that it is indicative that there are two causal theories on this short-list – most philosophers concede that causal relations between speakers and their environments have to play a fundamental role in a satisfactory theory of reference.) Proponents of [M] also have some specific problems to account for, over and above its general tendency to elicit the atavistic impulse that the question of reference has not really been addressed.

Much philosophical work continues on these problems, and these debates are not in danger of conclusive resolution any time soon.

Language can be used as a means of communication because (some of) its elements have meaning. But what is 'meaning' and what is communicated? These questions are complex, and have not always been carefully considered in psycholinguistics. Since the late 1970s, however, there has been a growing agreement that one thing – not the only thing – that is communicated is information about situations in a world. Sometimes that world is the real world, as in news broadcasts or conversations about what happened last night. Sometimes it is a fictional world, for example in novels and short stories, and sometimes it is an abstract domain, as in many articles in this encyclopedia. Communication about situations is primarily associated with literal meaning (and knowledge-based inferences from literal meaning), which is considered to be largely compositional. Communication therefore depends on mental representations of situations.

Situations comprise individuals with properties, and relations among those individuals. Some of those relations make up events, states, and processes (sometimes called, as a class, eventualities). These latter also stand in relations to one another, such as cause and effect. To convey information about situations, it is necessary to convey information about their component parts. To do so, it is necessary to refer to individuals, properties, and eventualities.

Reference is one kind of 'meaning of meaning,' though it is perhaps not the most obvious one. Another kind of meaning is sense, or connotation. The distinction between sense and reference, and the connection between them, was made explicit by the logician Gottlob Frege in the late 19th century. Frege was unimpressed by natural languages, and sought to construct a logically well-behaved language in which he could describe the logical foundations of mathematics. In this *Begriffschrift* (conceptual notation), meaning is compositional: The meaning of a complex expression is determined by the meanings of its parts and their method of (syntactic) composition. Sense (*Sinn*) corresponds roughly to conceptual content (or mode of presentation, as Frege sometimes put it). Reference (*Bedeutung*) is what an expression stands for (in any possible context of use). 'The morning star' and 'the evening star' are two modes of presentation of the planet Venus (expressions with different senses). In the real world, the two expressions have the same reference (or referent in more modern English parlance), Venus itself. Ideally, both sense and reference are compositional.

In ordinary language, it is natural to think of noun phrases, such as 'John,' 'the table,' and 'the book I lent you last week,' as expressions that refer to particular people or objects, at least when those expressions are used in appropriate contexts. However, in Frege's view, every expression has a sense and a reference. In particular, sentences have truth values (true or false) as their referents. Mathematical statements are either true or false. In everyday language, the truth of a sentence depends on the context in which it is used. Whether it is true that 'John is tall' depends on which John is being talked about. The other base point of Frege's system is the proper name, in an extended sense. In arithmetic, for example, '2' is a proper name for the number two. Proper names have objects as their referents. In the case of '2,' that object is an abstract object (Frege was a Platonist).

For Frege, and many 20th-century philosophers and logicians inspired by his work, objects (or entities) and truth values are the two basic semantic types. Montague (see Thomason, 1974), for example,

Language can be used as a means of communication because (some of) its elements have meaning. But what is 'meaning' and what is communicated? These questions are complex, and have not always been carefully considered in psycholinguistics. Since the late 1970s, however, there has been a growing agreement that one thing – not the only thing – that is communicated is information about situations in a world. Sometimes that world is the real world, as in news broadcasts or conversations about what happened last night. Sometimes it is a fictional world, for example in novels and short stories, and sometimes it is an abstract domain, as in many articles in this encyclopedia. Communication about situations is primarily associated with literal meaning (and knowledge-based inferences from literal meaning), which is considered to be largely compositional. Communication therefore depends on mental representations of situations.

Situations comprise individuals with properties, and relations among those individuals. Some of those relations make up events, states, and processes (sometimes called, as a class, eventualities). These latter also stand in relations to one another, such as cause and effect. To convey information about situations, it is necessary to convey information about their component parts. To do so, it is necessary to refer to individuals, properties, and eventualities.

Reference is one kind of 'meaning of meaning,' though it is perhaps not the most obvious one. Another kind of meaning is sense, or connotation. The distinction between sense and reference, and the connection between them, was made explicit by the logician Gottlob Frege in the late 19th century. Frege was unimpressed by natural languages, and sought to construct a logically well-behaved language in which he could describe the logical foundations of mathematics. In this *Begriffschrift* (conceptual notation), meaning is compositional: The meaning of a complex expression is determined by the meanings of its parts and their method of (syntactic) composition. Sense (*Sinn*) corresponds roughly to conceptual content (or mode of presentation, as Frege sometimes put it). Reference (*Bedeutung*) is what an expression stands for (in any possible context of use). 'The morning star' and 'the evening star' are two modes of presentation of the planet Venus (expressions with different senses). In the real world, the two expressions have the same reference (or referent in more modern English parlance), Venus itself. Ideally, both sense and reference are compositional.

In ordinary language, it is natural to think of noun phrases, such as 'John,' 'the table,' and 'the book I lent you last week,' as expressions that refer to particular people or objects, at least when those expressions are used in appropriate contexts. However, in Frege's view, every expression has a sense and a reference. In particular, sentences have truth values (true or false) as their referents. Mathematical statements are either true or false. In everyday language, the truth of a sentence depends on the context in which it is used. Whether it is true that 'John is tall' depends on which John is being talked about. The other base point of Frege's system is the proper name, in an extended sense. In arithmetic, for example, '2' is a proper name for the number two. Proper names have objects as their referents. In the case of '2,' that object is an abstract object (Frege was a Platonist).

For Frege, and many 20th-century philosophers and logicians inspired by his work, objects (or entities) and truth values are the two basic semantic types. Montague (see Thomason, 1974), for example,

who made the first detailed attempt to apply broadly Fregean ideas to natural language, followed Frege on this point. However, it has more recently been suggested (e.g., by Parsons, 1990) that eventualities and properties are basic semantic types (rather than derived types, as Montague and Frege claimed). For example, a property such as 'is an even number' is, for Frege, a function from objects to truth values (it maps 2 to true and 3 to false, for example).

Frege focused on proper names as expressions that refer to objects. What about expressions such as 'the bag,' often referred to as definite descriptions in the philosophical literature? Informally, it is natural to consider such expressions as referring to objects. However, a tradition going back at least to Bertrand Russell considers that definite descriptions are not referring expressions at all, but rather quantifier expressions used to state (in the case of a singular definite description) that there is one and only one entity that has a certain property. Thus, Russell was able to claim that 'the present King of France is bald' is false, if France has no king, because it asserts that France has one and only one present king.

Psychological Issues

The ideas presented so far may seem far removed from psychological considerations. However, if all expressions have (a sense and) a referent, and the sense and reference of complex expressions can be built up compositionally, word identification plus syntactic analysis can form the basis for semantic interpretation in language comprehension.

As has already been noted, natural languages do not behave like logical languages of the kind Frege studied. In mathematics, '2' always means the number two. In English, 'John' may be John Smith on one occasion and John Brown on another, even in the same text. Likewise, Russell's 'the present King of France' is an atypical definite description. There is only one France, and if a country has a king, it only has one. A more typical definite description, such as 'the cold cup of tea' will have different referents in different contexts (and no referent in many contexts).

Language is used in context. Part of the context, particularly in spoken language, is the nonlinguistic context in which the language is used. Another part is the linguistic context – what has been said or written so far. From a psycholinguistic perspective, what is crucially important is the mental representation of the context, whether linguistic or nonlinguistic, which mediates language understanding. This claim should not be mistaken for the idea that language refers to the mental representation rather than the real world. Rather, the claim is that, from a psychological perspective, language use must be regarded as mediated by mental representations.

Situation Models

Given the idea that language conveys information about situations in the real world, or fictional or abstract worlds, the relevant mental representations must represent those situations. Such representations are called situation models or mental models. Mental models must contain elements corresponding to the basic building blocks of the world (entities, properties, eventualities, truth values, or whatever) and there must be computationally tractable methods for constructing them. A single clause usually presents an eventuality, whose type is determined by the verb. Entities are typically introduced by noun phrases in various syntactic positions and playing various thematic roles. Local 'who did what to whom' information can be constructed compositionally. Relations between eventualities are sometimes indicated explicitly, for example by the use of connectives such as 'but,' 'because,' and 'however.' Sometimes they are implicit and can only be computed by using background knowledge.

Psycholinguists have not paid a great deal of attention to questions about what different types of expression refer to. They have assumed that local 'who did what to whom' information is computed, perhaps with reference to background knowledge, and then integrated (again perhaps using background knowledge) with other bits of 'who did what to whom' information from elsewhere in the text.

Coordination between Speakers

One issue that has been investigated in psycholinguistics is how speakers coordinate with one another to ensure successful reference. When a speaker talks about an object or a writer writes about one, the addressee must correctly identify the object being talked about if communication is to be successful. In many cases nonverbal context plays a crucial role in such coordination: speaker and addressee are looking at, or handling, the same object, for example, while talking about it. However, not all cases are so straightforward. Johnson-Laird and Garnham (1980) identified some very general considerations that help to determine successful reference, for example whether an addressee will recognize that a particular description (e.g., 'the man I met last night') refers to a particular person. More recent work on dialogue has found that while speakers may not consider the knowledge that they share with their addressee (common ground) when initially planning an utterance (Horton and Keysar, 1996), under normal discourse

conditions utterances often ultimately reflect the common ground between an speaker and hearer (Clark, 1996). Furthermore, over successive turns in a dialogue, interlocutors will coordinate the use of different expressions, converging on a single means of referring to a particular object (Garrod and Anderson, 1987).

Anaphoric Reference

Another issue that psycholinguists have looked at in some detail, and perhaps the major question about reference that they have concerned themselves with, is that of second and subsequent reference to the same entity, via pronouns or other anaphoric expressions. One piece of 'who did what to whom' information might be that John sent a letter to Jill and the next piece might be that he hoped she would receive it the next day. To an English-speaking reader it will be obvious that 'he' is John, 'she' is Jill, and 'it' is the letter that John sent to Jill. However, it is not apparent just from the form of the expressions 'John' and 'he' that they refer to the same person and, indeed, in many contexts they would not, for example (1).

(1) John confessed to Bill because he offered a reduced sentence.

Anaphora is not confined to coreferential noun phrases, though such cases are the most commonly studied in psycholinguistics. As well as identity of reference anaphora, there is identity of sense anaphora, which includes most uses of indefinite pronouns, as in (2), and some uses of definites, for example in 'paycheck' sentences such as (3).

(2) John has eaten a big bowl of vanilla ice cream and now Judy wants some.

(3) The man who gives his paycheck to his wife is wiser than the man who gives it to his mistress.

Here, 'it' is a paycheck, but not the one that was referred to in the first part of the sentence. Furthermore, not all anaphora is nominal. English, in particular, is rich in verbal anaphors, such as the verb phrase ellipsis in (4).

(4) I have always wanted to travel to China and next summer I am going to.

Verbal anaphors are typically identity-of-sense anaphors, and many of them are ellipses in the technical sense of Sag and Hankamer (1984): what is elided or replaced by a verbal anaphor must have an exact counterpart in the surrounding, usually preceding, text.

Another issue is that some uses of definite noun phrase anaphors, and in particular pronouns, are analyzed as bound variables, and not as referential expressions, as for example in (5).

(5) Every dog loves its owner.

However, the parallel between (5) and (6) suggests that they should, perhaps, be treated similarly, which they are in theories such as discourse representation theory (Kamp and Reyle, 1993).

(6) Fido loves his owner.

Psychological accounts of anaphoric reference are concerned with the mental mechanisms, representations, and processes that underlie the production and comprehension of anaphoric reference. They must be informed by linguistic accounts of how and when different types of anaphoric expression can be appropriately used. However, they must also be subject to empirical tests in psychological studies generating standard types of psychological data. Linguists describe the morphosyntactic properties of anaphoric expressions, such as gender and number marking on definite pronouns, which affect their interpretation. They also describe syntactic constraints on the interpretation of pairs of noun phrases as (possibly) coreferential, for example through the principles of binding theory. At a higher (discourse) level, attempts have been made to specify constraints on the form that anaphoric noun phrases should take. Some researchers have considered the accessibility or givenness of the antecedent (e.g., Ariel, 1990; Gundel *et al.*, 1993) to account for when particular forms are required or permissible, and we shall return below to other accessibility- or focus-based accounts of the form of referring expressions. Others have considered the discourse function of anaphoric forms in order to account for their use, including the purpose of particular forms, such as the demonstrative 'this X' to refer to antecedents currently out of focus, and overspecific forms (e.g., a proper name when a pronoun would be sufficient for identification) to shift discourse topic (e.g., Vonk *et al.*, 1992).

The most straightforward kind of reference is to people, animals, and objects. It therefore seems likely that reference to such objects is mediated by representations in which those people, animals, and objects are represented. Mental models (or situation models) are representations of this kind. People talk about situations in the real world or in imaginary worlds or abstract domains, and mental models of these situations can be used to guide the selection of referring expressions, and can be constructed and modified in response to the comprehension of referring expressions. There must, therefore, be a set of procedures for generating referring expressions from mental models and for generating and modifying mental models on the basis of referring expressions. In addition, items can

be represented in mental models on the basis of perceptual information.

On one view, once an item is represented in a mental model, anaphoric expressions might make direct contact with their representations in comprehension, which need not be tied to the particular linguistic expression used to introduce them. Sag and Hankamer (1984) proposed that definite pronouns and other deep or model-interpretive anaphors worked in just this way. They also proposed that many verbal ellipses were indeed ellipses, and had to be interpreted by effectively copying part of a fairly superficial representation (Logical Form, in their view) of a piece of nearby text. Garnham *et al.* (1995) showed that, at least when a pronoun is fairly close to its antecedent, the linguistic form of the antecedent expression does affect the interpretation of definite pronouns. However, this could be because mental models contain information about how their elements have been or might be referred to. Garnham and Oakhill (1987) have also shown that the interpretation of ellipses can be influenced by an underlying mental model, in a way not allowed for by Sag and Hankamer. Another line of evidence supporting the idea that anaphoric expressions take their meaning via mental representations of objects rather than linguistic descriptions of those objects comes from the study of indirect reference in which the referent of an anaphor is not explicitly mentioned in previous text, as in (7).

(7) James tried to write to Alison many times, but always tore them up in the end.

In this case, a previous antecedent trigger ('write'; Cornish, 1999) makes the referent ('letters') available for anaphoric reference ('them') by allowing it to be represented in the mental model of the text. If reference depended on the literal text then such indirect reference would be impossible; however, some researchers have reported it to be relatively common (Yule, 1982).

Perhaps the most important factor in anaphoric reference is focus. As we mentioned earlier, in natural languages, unlike the logical languages studied by Frege and others, the interpretation of referring expressions is often highly context dependent. A simple definite description such as 'the bird' is referentially highly indeterminate out of context, but in a particular text or conversation it can readily be used to refer to a particular individual bird. Because mental models are specific to individual texts, they help to explain this fact. However, in a text of any length an expression such as 'the bird' might refer to different individuals on different occasions, suggesting that mental models are partitioned and that different sets of individuals are more salient at different points in the text. Furthermore, depending on the particular local structure of the text, an individual that could be referred to as 'the bird' might be more appropriately referred to as 'it' or 'Joey' or 'the parrot or 'the large bird.' Attempts to explain these facts, both from the point of view of production, or selecting appropriate referring expressions, and from the point of view of comprehension, or how difficult certain referring expressions are to interpret in different contexts, are usually discussed in terms of the accessibility, prominence, or focus status (in the psychological, rather than linguistic sense) of the antecedent.

The work of Grosz, Sidner, and others (see especially Grosz and Sidner, 1986) has led to the distinction between global and local focus. Global focus is related to episode structure (Anderson *et al.*, 1983), or more generally to that of discourse segments and their relations to one another. As Sidner (1983) and others have pointed out, in narratives and other texts about people, protagonists are important in determining focus, though Grosz and Sidner subsume such effects under more general principles. Anderson *et al.*'s (1983) episode structure effects are linked to the status of protagonists, as is the finding that proper names produce a stronger focusing effect than definite noun phrases.

Local focusing is particularly important in determining which recently mentioned people (or things) would preferentially be referred to pronominally. Centering theory is a theory of local focusing that has been developed within Grosz and Sidner's framework. It is couched as a theory of how attention shifts within a discourse segment. It identifies, within any utterance, a set of forward-looking centers, or things likely to be rereferred to in the upcoming discourse. It also identifies one backward-looking center, which is the current (local) topic, and which should be the same as one of the forward-looking centers of the previous utterance.

Centering theorists have made various attempts to specify when references should be pronominal. An early view, which focused on the idea that the backward-looking center should be pronominalized (particularly if it picks up the highest ranked forward-looking center of the previous utterance), led to a series of experiments by Peter Gordon and his colleagues on the repeated name penalty (Gordon *et al.*, 1993 and later work), a difficulty in comprehension caused by repeating a proper name or a common name rather than using a pronoun. Gordon found empirical evidence for this effect, particularly for anaphors in syntactic subject position, and when there was not a shift of center. However, later versions of centering theory have, on empirical

grounds, relaxed the pronominalization rule to say merely that if any of the forward-looking centers of the previous utterance are pronominalized in the current utterance, the backward-looking center of the current utterance must be pronominalized.

A different approach to focusing, and the way it affects anaphoric reference, is found in Amit Almor's (1999) informational load hypothesis (ILH), which is founded more directly in psychological research than is centering theory. The ILH asks: what factors make a particular form of anaphoric reference easy or difficult to process, given the context in which it occurs and, in particular, given what its antecedent is? According to Almor, three factors are important: the focus status of the antecedent, whether the anaphor adds new information about its referent, and the informational load of the antecedent–anaphor pair. From the examples he considers, Almor appears to be investigating local focus, and in his experimental work he focuses items using wh- and it-clefts, which are thought to mark contrastive focus. Informational load is the crucial new concept in this hypothesis and it is defined in terms of the conceptual distance between antecedent and anaphor, with conceptual distance taken to be positive when the antecedent is less specific that the anaphor ('... the bird ... the robin ...') and negative when it is more specific ('... the robin ... the bird ...'). Thus, for anaphors that are less specific than their antecedents, informational load decreases (by becoming more negative) as conceptual distance increases. Informational load can be justified if the antecedent is not in focus, as it helps to reactivate the representation of the antecedent. Indeed, previous work by many researchers supports the idea that increased overlap between an antecedent and its category anaphor aids in anaphor resolution, with more typical antecedents (e.g., robin) for a given category (e.g., bird) leading to faster processing times for the anaphor compared to atypical antecedents (e.g., ostrich). However, when the antecedent is in focus the increased information load produced by semantic overlap is not justified. According to Almor, informational load arises because semantic overlap in working memory produces an interference effect, just as phonological overlap does, and this interference competes with the facilitatory effect of semantic overlap just described. Thus, the ILH leads to the surprising prediction of an inverse typicality effect in anaphor resolution for focused antecedents. Since 'ostrich' is conceptually more distant from 'bird' than 'robin' is, the pair '... the ostrich ... the bird ...' has a lower (more negative) informational load than '... the robin ... the bird ...,' and the former pair should be easier to process. With clefted antecedents, Almor reports this result.

In our own lab we have failed to replicate this result consistently with a typicality manipulation, though we have shown it in a category hierarchy, where the conceptual distances are clearer ('...the cobra...the reptile...' is easier than '... the snake ... the reptile ...'). However, we have been unable to find evidence for semantic interference in working memory.

In describing the ILH, Almor does not discuss the effect of multiple possible antecedents for an anaphor. However, potential antecedents that turn out not to be antecedents ('Phil' in [8], for example) affect anaphor resolution.

(8) Jack threw a snowball at Phil, but he missed.

Gernsbacher (1989) showed that once an anaphor was resolved, the nonantecedents were suppressed, and that, for pronouns at least, this process took some time. Garrod *et al.* (1994), however, suggested that pronouns could be resolved immediately if they referred unambiguously to focused main characters.

The ILH tries to provide an integrated account of the ease of processing of noun phrase anaphors of various types. In this respect it differs from previous work, which has tended to produce lists of (apparently independent) factors that affect the ease of interpreting anaphoric reference. One such factor is the distance between a noun phrase anaphor and its antecedent, which is particularly important in the case of pronouns. However, it is likely that foreground or focus interacts strongly with this factor, since material intervening between a pronoun and its antecedent is likely to shift the focus away from the antecedent. A related issue is the interaction of distance and working memory, or how near is 'near'? Ed O'Brien (e.g., 1987) has emphasized the need to distinguish between potential antecedents that are still likely to be represented in working memory and those that are not.

Another factor that has been investigated in the case of pronoun resolution in particular is implicit causality. When a pronoun occurs in a statement of an explicit cause following the description of an interpersonal event, the interpretation of the pronoun can depend on the verb used to describe the interpersonal event. For example, in (9) 'he' is likely (though not certain) to be taken to refer to Bill, whereas in (10) it is likely to refer to John.

(9) John blamed Bill because he...

(10) John called Bill because he...

Garnham *et al.* (1996) suggested that this effect might be a focusing effect, but found no evidence in favor of this view. Rather, it appears, in the comprehension of a completed sentence, to reflect how easy it is to integrate the information in the 'because' clause

with the information in the main clause. Thus, a complete sentence such as (11) is easier to process than a sentence such as (12).

(11) John blamed Bill because he had been careless.

(12) John blamed Bill because he needed a scapegoat.

Implicit causality effects may be an example of the use of world knowledge in the interpretation of pronouns, as indeed may the more general effect of the coherence relations between clauses or sentences, which as we mentioned above are often signaled by connectives, on anaphor resolution.

Other factors that have been found to influence anaphor interpretation are more formal, and are possibly used as fallback strategies when content-based strategies fail. These strategies include parallel function (taking the referent of an anaphor to be the item in the preceding clause that plays the same grammatical role as the anaphor in its clause), and preference for syntactic subjects or first-mentioned items in preceding clauses as antecedents for anaphors in the current clause (though preferences for syntactic objects have also been reported, often depending on the prosodic stress given to the anaphor). Parallel function effects are strongest when the syntactic parallelism between the clauses is strongest. They are interesting because they are difficult to accommodate in both centering theory and Almor's ILH.

The strongest evidence for an overall preference for (unaccented) pronouns to be taken as referring back to an antecedent when it has been mentioned first compared to other possible antecedents comes from probe word tasks (Gernsbacher and Hargreaves, 1988). However, there is evidence that this preference may be an artifact of the testing procedure.

While these factors have been proposed independently of more general theories such as centering theory and the ILH, many of them could be taken up under the notion of focus within these theories. For example, centering theory proposes that an utterance's forward-looking centers are partially ordered to reflect which ones are most likely to be referred to again. This ordering may be based on factors such as syntactic position (indeed, the highest ranked forward-looking center has often been assumed to be the grammatical subject of the sentence). In the ILH, such factors also affect focusing.

Finally, it should be noted that while syntactic considerations undoubtedly influence reference, the reverse can also be true: there is evidence that syntactic processing is influenced by referential considerations. In a story about two women, the noun phrase 'the woman' is likely to be referentially indeterminate. So, although a 'that' clause is preferentially interpreted as a complement clause rather than a relative clause, if a postmodifier is needed to disambiguate a reference, this preference may be overridden, even in initial parsing (Altmann *et al.*, 1992).

Summary and Conclusions

A psycholinguistic perspective on reference focuses on the mental representations and processes that underlie people's ability to use language, both as speakers and writers and as listeners and readers. Mental representations mediate references to things in real, imaginary, and abstract worlds. Linguistic and philosophical analyses bring to light some of the complexities that psychological theories must take account of.

A major concern within psycholinguistics has been to explain second and subsequent anaphoric references to the same person or thing. A variety of factors have been identified as influencing this process, and more recently the more unified approaches of centering theory and the informational load hypothesis have been suggested. These approaches are best located within a mental models framework that stresses the importance of representations of situations in the world as mediating language processing.

Frege's Legacy

Classical theories of reference assume a strong connection between a sign, its meaning, and its reference. A word connected to a particular object embodies a description containing a rundown of the object's properties. This is to say that a word possesses the capacity to evoke in the mind a cluster of properties that serve to specify the nature of the object to which the word refers. Knowing the meaning of a sign is knowing how it refers, and knowing how it refers is presumably knowing truth – all of which can easily land one in a vicious circle.

Gottlob Frege simplified this formula. He drew a distinction between 'sense' (*Sinn*) and 'reference' (*Bedeutung*). Sense is grasped when a sign is understood, and this sense determines its reference. Frege is often regarded as the prime initiator of 'logicism' – the wedding of logic and mathematics, with the former hopefully becoming the patriarchal repository of all thought and the latter the queen of the sciences. This grand project called for a divorce of signs in general

Frege's Legacy

Classical theories of reference assume a strong connection between a sign, its meaning, and its reference. A word connected to a particular object embodies a description containing a rundown of the object's properties. This is to say that a word possesses the capacity to evoke in the mind a cluster of properties that serve to specify the nature of the object to which the word refers. Knowing the meaning of a sign is knowing how it refers, and knowing how it refers is presumably knowing truth – all of which can easily land one in a vicious circle.

Gottlob Frege simplified this formula. He drew a distinction between 'sense' (*Sinn*) and 'reference' (*Bedeutung*). Sense is grasped when a sign is understood, and this sense determines its reference. Frege is often regarded as the prime initiator of 'logicism' – the wedding of logic and mathematics, with the former hopefully becoming the patriarchal repository of all thought and the latter the queen of the sciences. This grand project called for a divorce of signs in general

and most particularly of arithmetical signs from 'psychologism.' The idea was to purify language, to rescue it from the swamp of semantic muck into which it had presumably wandered, and to use it against itself in elevating it to clarity and precision. According to Frege and all kindred thinkers, if language could be liberated once and for all time from vagueness, ambiguity, and sticky generalities, it could become a respectable instrument of unequivocal thought. It could be used to paint a faithful 'picture' of any and all meaningful states of affairs. In other words, by 'logicizing' language, its weaknesses could be strengthened, its blemishes could be erased, and future mistakes could be avoided. From the Olympian reaches of the highest rooftops, the world could eventually be seen from a detached God's eye view.

So, the task Frege set for himself by way of this 'sense/reference' distinction was monumental: to establish a method for determining linkages between the objective world and its representation in signs. Equality of meaning of different signs referring to the same object became the watchword. The dilemma was that Frege's grand game plan involved rendering two virtually incompatible domains virtually equivalent: language, on the one hand, and the furniture of the world, on the other. Frege argued that, although two signs with the same reference – *Venus*, for example – could have two senses (the 'morning star' and the 'evening star'), two signs with the same sense could not enjoy the luxury of different reference.

By way of definitions, the 'intension' (sense) of a sign consists of the conception of the sign, irrespective of that to which it refers. 'Extension' (reference) consists of the things to which that conception refers. Intension used in this context must be distinguished from 'intentionality,' a phenomenological term entailing the property of consciousness whereby it refers to or intends an object. The intensional object is not necessarily existent, but can be merely what the mental act is about, whereas extension presumably involves the 'real' furniture of the objective world.

Thus, 'Venus is Venus' is a tautology. In contrast, 'That star up there in the dark expanse is Venus' is not. It bears reference, extension. 'The evening star is Venus' has both reference and sense, intension. However, 'The morning star is Venus' also sports reference and sense. Reference is one ('Venus'), but sense is two ('evening star,' and 'morning star'). Yet, Frege assured us that no problem exists inasmuch as we specify 'reference' to objects in the physical world, so it is still smooth sailing toward clear and distinct thinking and meaning. Apparently, the relations between Frege's signs and the world are not characterized by symmetry, but by asymmetry. However, this problem was in a manner of speaking pushed under the rug, for the sign's intension (sense) was highlighted somewhat at the expense of extension (reference), and language itself, that apparently ubiquitous partner to mind, held the trump card. This outcome is what we might have expected, since Frege stacked the deck from the beginning.

More questions arise: do sentences impart any information regarding their presumed objects of reference (*Venus*, *morning star*, *evening star*), or simply about the signs themselves ('Venus,' 'morning star,' 'evening star')? If the latter is the case, then why do we like to be comforted by the soothing idea that 'reference' is fixed while meanings may suffer alterations? If meanings change, how can signs actually 'refer to' the same things in the world? If signs do not necessarily refer to the same things but to variable 'semiotic entities,' then do the 'real' things of the world actually make much difference regarding meaning? Can meanings be something found in things referred to, or are meanings embodied within their respective signs? Or in the final analysis, do words hook onto worlds?

The dilemma coiled within Frege's project soon became obvious. No real feeling and thinking mortal could expect to survive in the Fregean desiccated world that afforded absolute purity of expression. If all fuzzy edges could somehow be smoothed for all time, then eventually even the artist's brush would run dry, the musical score would contain no notes, the dance troupe would be paralyzed, the poet would be condemned to silence and the blank page, and science would find itself suffering from interminable catatonia.

Actually, the demarcation between Frege's 'object' and 'reference' is quite tenuous. It seems safe to say that the idea of 'reference' is not coterminous with the percept and concept of a 'referent.' More adequately stated, it entails the act of referring, or better, the act of interrelating. Once the act has occurred, an 'object' then bounds onto the scene, which is now the incorporation of what is in the Fregean tradition called the sign's 'reference.'

Referential Paradise Lost?

In addition to Bertrand Russell's critique of Frege, Willard V. O. Quine upended the Fregean dream of clear and distinct reference with his 'inscrutability of reference' thesis. Quine *qua* lay physicist conceded that, in point of epistemological footing, physical and mental objects differ only in degree: Both interact with our general conception of things as cultural posits (1953). Yet, he placed greater stock in physical objects than he did in, say, Homer's gods. Physical objects are epistemologically superior to purely

mental constructs insofar as they have in the past proved more efficacious as a device for ordering the flux of experience. Lest our confidence run rampant, however, we are reminded that physicalism provides us with no guarantee.

Quine argued that not only does sense not determine reference but that sense is itself indeterminate, as is reference. In his classical example, a field linguist overhears "Gavagai!" from the mouth of a native informant when a rabbit is sighted scurrying through the bushes, and the linguist cannot know whether the word means 'rabbit,' 'undetached rabbit parts,' or 'a rabbit space-time stage.' Because each of these phrases has different extensions, reference to 'Gavagai!' remains radically indeterminate. If this holds true of someone else's language, it is also true of one's own language when one is conversing with a fellow language user. How is one to know if the other person is using her words in the same manner one would be prone to use them? Quine's elaborate argument leads to the conclusion that we must give up the idea that we can refer determinately to that of which we think we speak. However, we are left with a queasy feeling. Quine wrote quite convincingly about the indeterminacy of reference; however, he did so by talking about 'rabbit,' 'rabbit parts,' and 'rabbit stages' as if his words enjoyed some sort of reference or other. Indeed, the very assumption that we cannot refer determinately to the furniture of our world presupposes that we can somehow refer by the fact of our talking about the furniture of our world when claiming we cannot refer to the furniture of our world. In a manner of putting it, the indeterminacy of reference cannot be said, yet we can apparently say it.

What is Quine's solution? Bite the bullet and concede that the very idea of reference is meaningless. Saving grace can be had, Quine has told us, if we have a background language against which to gauge the meanings of the words in the target language. The sentence, "Gavagai!" refers to rabbit in what sense of 'rabbit?' kick-starts a regress, and we need a background language as a fulcrum point to regress into so that the regress will not continue unabated. The background language gives words in the target language sense, if only relative sense: sense relative to the background language. Demanding determinate reference would be like quantum physics demanding *both* determinate position *and* velocity, rather than *either* position *or* velocity relative to a given frame of reference – the background language. So, we acquiesce to our mother tongue, take words at face value, and do the best we can with what we have.

Yet, why, we might ask, should we have faith in our mother tongue?

A Retreat into Imaginary Worlds and Language in Search of an Answer

Historically, extension has been supposedly upfront and stalwart, intension uncertain and anemic. However, Quine claimed that both are inscrutable. Of course, within the parochial confines of our own language, extension continues to seem more reliable than intension. However, this is not necessarily so: The empirical determinacy of extension, through time, cannot even be guaranteed within our own language. Thus for Quine, and, more recently from another vantage point, that of Jacques Derrida (1973), there is no experience that can provide data with which a statement can be absolutely verified. There are no data, because there is no absolute 'immediacy' or 'presence.' This lack renders the meaning of the most basic of statements such as "That raven is black" simply undecidable, for such statements do not refer instantaneously to some independent empirical entity in the 'real' world. We can do no more than gather up an unruly collection of unfixed meanings and muddle along. Reference is ultimately imaginary, or at most it is a linguistic act.

Most Fregeans of a positivist bent contended that, regarding imaginary constructs or fictions, there can be no meaningful concern for reference or truth. Recently, a new generation of language philosophers and literary theorists has undertaken the analysis of reference in fiction; their efforts often have been governed by contrived explanations of the difference between normal reference and the presumably aberrant, abnormal practice of reference to nonexistent objects. Literary theorist Thomas Pavel (1986), for example, argued that there *is* reference to fictional worlds, whether the 'objects' contained within them exist in the 'real' world or not and whether they are possible or impossible 'objects.' He brandished his idea that normal and marginal referential practices are different in degree rather than in kind because they display many identical characteristics: Fictional reference is by no means a logically strange activity, but rather is a close cousin to our conventional manner of making reference. Although at one point Pavel admitted to a 'complex and unstable' relationship between texts and worlds and between the 'real' world and fictional worlds, he suggested a deep-seated, tacit human assent toward 'textual realism'; this is rooted in our very nature to the degree that we tend to compensate for the lack of referential immediacy "by the strength of our ontological commitments," for we confidently "regard our worlds as unified and coherent, our fits of ontological prodigality notwithstanding" (Pavel, 1986: 73).

The notion of imaginary or fictive reference as a linguistic act tends to historicize reference, to render it a matter of language conventions: How we use our words determines that to which they refer. This is also to assume that extension enjoys no necessary priority over intension. Richard Rorty (1982) also historicized reference. Our ancestors, he wrote, believed in many things that do not really exist – they are purely intensional objects the likes of which we label 'unicorns,' 'werewolves,' 'mermaids,' and such. Ordinarily, we tend patronizingly to dismiss these hapless predecessors; they were steeped in prejudice and superstition. Century after century, they failed to name the 'real,' whereas we somehow would like to believe we are finally getting things right. However, Rorty argued that the traditional notion of reference provides no axiom by means of which to solve the problem of our ancestors invariably being wrong while we are largely right. On so doing he referred to three senses of 'refer.'

Hilary Putnam's (1990) 'opaque' A-reference is commonsensical: It involves things we refer to not by 'metaphysical realism' but by the very act of thinking we are referring to them (including nonexistent entities), which is what Putnam termed 'internal realism.' 'Transparent' B-reference is of the Bertrand Russell type in the sense that only what exists can be referred to, the technical use of the term generally being limited to linguistics and philosophy (or, in Putnam's words, 'metaphysical realism'). C-reference entails something like what Thomas Pavel (1986) called 'mixed sentences.' The statement, 'Jove's thunderbolts are actually electrical discharges from the clouds,' includes both our misguided ancestor's A-reference ('Those are Jove's thunderbolts') and our own enlightened and presumably superior B-reference ('Those are nothing but electrical discharges from the clouds'). The question Rorty asked is: How was perennial ancestral error suddenly seen as error by means of its alteration to produce an apparent truth? The best we can do is to assume our ancestors did the best they could, expect the same of ourselves, and trust our descendants will do likewise.

If we apply Rorty's notion to the idea of fictive worlds and their interpretation by successive communities of literary addicts, we might surmise that the *Don Quixote* our ancestors read 'referred' to a relatively limited fictive space, the borders of which were expanded with subsequent readings by future readers. Consequently, our *Don Quixote* world is exceedingly vast in comparison with that of our ancestors. In this vein, previous readings of Cervantes's masterpiece actualized a certain part of the potential representing the novel's fictional universe, whereas current readings are capable of actualizing a greater portion. But are they? Our ancestors' form of life had myriad facets, many of which are not known to us or are simply no longer accessible to us. Of course, our readings are contextualized within the numbing complexity of our contemporary milieu, in addition to our awareness of intertextual implications. Yet, our ancestors had their own access to the intricately woven fabric of their oral tradition, as well as the literary works of their day, some of which we have relegated to the attic. Do not readings separated by vast expenses of space and time become radically distinct? Can there be a set of criteria for determining the magnitude of textual fictive space?

In view of these difficulties in conceptualizing an ontological framework for fictions, one might tend to concur with Rorty that over the long haul reference is pointless. All we need is the common sense notion of 'talking about' – A-reference – according to which the criterion for what a statement is 'about' is, in varying degrees of approximation, whatever we think we are talking 'about.'

Our Fallible Limitations

Yet, perhaps Rorty's commonsensical talking 'about' some-*thing* and therefore merely talking and somehow getting along swimmingly is tantamount to Pavel's counsel that we minimize indeterminacy of reference and the incompleteness of all worlds by gracefully acknowledging their complexity and risking "the invention of a completeness-determinacy myth." The example of *Don Quixote* is once again evoked. Our venerable Hidalgo reads the world around him according to novels of chivalry, regardless of empirical evidence disproving his hypothetical framework. However, in a sense his hypothesis is correct. After all, he manages to succeed "in the detailed construction of a coherent, if precarious and incomplete, world version" (Pavel, 1986: 111).

Granted, Cervantes's hero packed his universe into the Procrustean bed of 16th-century prose. In so doing, he read fiction as if it referred to the real, serving as a warning to all readers, whether they are engaged in reading the text of the universe or the universe of texts. A certain 'referential fallacy' surfaces here. Regarding our present-world version as the field of reference, which we would by and large like to take as 'real,' there is no guarantee that we somehow got things right. Therefore, if in the sense of Karl Popper (1963), confirmation is inevitably failed refutation, we must go on being wrong with the idea that in the long run somehow we will be able to succeed. Regarding our textual worlds offering up their points of reference to us, which we take to

be fictions and 'irreal' and perhaps at their best 'real' by proxy, no matter how complete our interpretation may take us, there will always be some way to take it a mite further. Either way, pinning our words and signs onto whatever imaginary or physical world or worlds lie before us is at worst inconsistent and at best it remains an incomplete project. This 'referential fallacy' is not of the Umberto Eco (1976) sort (for a critique of Eco's argument against the notion of reference, see Ponzio, 1993; Knuuttila, 2003).

Alternatives Emerge

In a last-ditch effort to salvage the idea of reference, we have the 'causal theory,' which at the same time delivers a death certificate to any and all attempts to derive reference from a description of the object of a word's properties or attributes.

The causal theory says words, and all signs for that matter, refer to the furniture of the world in terms of historically determined causal chains involving that furniture and our linguistic – and general semiotic – representations of them. This theory demands nothing less than the condition by means of which one part of the world is semantically related to another part. This is a tall order indeed, and it can place us in a quandary. How many possible causal chains are there for a particular sign and its representation? One culture's, and even one person's, causal chain is another culture's or person's falsity, absurdity, nonsense, or merely silliness. What a causal theory needs is a corollary of counterfactuality; a causal theory must specify reference in conditional terms: What would be the case were certain causal relations to inhere?

Now enter Donald Davidson (1990). Davidson tossed 'reference' into the trash bin of misused concepts. He would like to convince us that reference, whether intensionally or causally construed, cannot support the entire conceptual weight of a theory of interpretation. He alluded to Alfred Tarski's (1956) theory of truth, the paradigm case for which is his T-sentence: '"Snow is white" if and only if snow is white.' The Tarskian assumption has it that truth is explicable in terms of reference. With respect to the T-sentence, truth is determined by inspection of the object of reference; truth is explicable in terms of reference.

However, Davidson, in disagreement with Tarski, had no use for such a correspondence theory of truth. He abandoned reference altogether, but held tight to the idea of truth. Availing himself of the 'Principle of Charity,' he argued that truth for one human speaker and truth for another human speaker will always have enough in common for them to find common ground and so they will be able to communicate. Truth, in other words, is a matter of belief, and belief is somehow dependent on the nature of the world. Since the world is a certain way, one speaker cannot interpret another speaker as believing that the world is any way other than the way it is. This is to imply, it would seem, that a human language is a language only on the premise that it can be translated into – and thus interpreted by – another human language. Translation is tantamount to interpretation, and interpretation arises out of beliefs regarding what is true and what is not true, regardless of what might be taken as reference. Fortunately for us, human speakers in the Davidsonian theory will be more rational than irrational, more logical than illogical with respect to their beliefs about the world.

All this is to take the furniture of the world as not some fixed collection of things out there that are waiting for words properly to be slapped onto them. Yet, speakers usually take the world, their world, for what it is, as if it were quite fixed. Davidsonian theory also takes human speakers as generally correct, and any error or disagreement is dependent upon their general correctness. The problem is that error and with it disagreement are not merely possible but actual, for whatever is known of the world is incomplete, and if presumably complete, then it will often be inconsistent. However, there will always be alternatives from which we stand to learn something more.

This brings us once again to Putnam. Putnam's meaning is neither in the mind, nor the sign, nor the conduit of information flow between signs and speakers and speakers, nor in the thing to which the sign presumably refers. There is no God's eye view of a fixed world replete with mind-independent objects, acts, and events. Signs do not by their nature hook onto things; neither do they correspond to things. Neither does mind create the hooks or establish the correspondence. Rather, "The mind and the world jointly make up the mind and the world" (Putnam, 1981: 55). If we can speak of reference at all, it is reference with respect to the interdependent, interrelated interaction among mind, sign, and world, within the whole of all contexts, both actual and possible, and past, present, and expected in the future. We must take the world, our world, as objective ('external,' 'real,' 'mind-independent'), for it is the only world we have for the moment; yet, we must acknowledge that it could always be taken for something slightly to radically different, so it is 'ideal' ('internal,' 'mind-dependent'). Now, how can we hope to integrate this assertion with the notion of reference?

Reference within the Triadic Concept of the Sign: Peirce

Frege's 'sense' embraced the notion of understanding, and understanding a language cannot be divorced from knowledge. So a theory of knowledge would seem to be in question. In this manner, a theory of sense should be a component of a general theory of knowledge, and knowledge in this respect should involve the idea of 'truth.'

This is not entirely the case, however. The Fregean reference of a name implies the bearer of that name, the object. To know 'reference' is to know the object, but not necessarily to know the 'truth' of the object. Knowledge of objects, acts, and events is not tantamount to knowledge of the 'truth' of those objects, acts, and events. It is, rather, knowledge of the linguistic use of words that interrelate with those objects, acts, and events. 'Sense,' it would seem to follow, is a matter of understanding how those words are used. This linguistic manner of distinguishing between sense and reference serves to liberate us from a psychological interpretation of meaning and from worry about the ontological status of sense and the objects, acts, and events of reference.

Then, do sense and reference give us a way of recognizing or identifying objects, acts, and events as the bearers of sense and reference? If that is the case, then where are interpretation and understanding: in those very objects, acts, and events; in the words or signs used; in sense and reference; or in the medium carrying those words? Obviously, Frege discarded psychologism, so interpretation and understanding are not in the head. He also had little need for ontology, so they are not in the objects, acts, and events. Neither are they exclusively within the words or signs nor in the communicative meaning (marks on pages or sound patterns in the air). Interpretation and understanding come about within the sentential context; 'The morning star,' 'The evening star,' for example (McDowell, 1993). Yet, such understanding involves words and things; it is basically a dyadic affair, as are the majority of the theories of reference that have popped up since Frege.

That much said, briefly consider Charles S. Peirce's concept of the sign, which is indelibly triadic. Peirce's sign consists of a 'Representamen' (akin to what usually goes by the name 'sign'), an 'Object' (a 'semiotic entity' as some physical object, act, or event is perceived, conceived, or imagined), and an 'Interpretant' (roughly comparable to the interpretation or meaning of the sign emerging from Frege's 'sense'). However, in the Peircean sense an Interpretant, once at least tentatively understood, can then become a sign in its own right. The same can be said for the Object

Figure 1 Peirce's conception of the three-dimensional tripodic sign.

as it is 'semiotically' perceived, conceived, or imagined by some interpreting agent. In this manner, neither reference nor meaning is fixed, for signs are processual.

Thus, Figure 1 depicts a three-dimensional tripod, not a triangle. The tripod illustrates that each sign component interrelates with its pair of companions in the same way they interrelate with each other and with it. Where are reference and the referent located? The question reveals the problem. There is no location. There is only interdependent, interrelated, interactive triadicity. So, where do sense, meaning, interpretation, and understanding take place? Once again, there is a problem with language. They do not 'take place,' for there is no specifiable 'place.' Interpretation, meaning, and understanding are not in the head; the signs; the objects, acts, and events; or in the communicative medium. They are in the entire context, which includes body and mind (*bodymind*) of the semiotic subject or agent. Moreover, they are always becoming something other than what they were becoming – this feature puts them within the now gently flowing, now undulating, now bucking and unruly semiotic stream of Peirce's process philosophy.

How can one account for this apparently disorderly universe of reference and meaning making? In the first place, understanding a language and other sign uses, sense and reference, and meaning making does not necessarily entail explicit knowledge of some theory. The knowing semiotic agent implicitly knows how to make meaning with the tacit assumption that sense and reference are somehow in the meaning making and so gets on with the task with no further ado. There is hardly any demand for describing and explaining what is done. It is just done because the semiotic agent knows what to do and does it. At the same time, because the agent does not ordinarily use nor needs to use some hard-rock theory, rules for doing what she does cannot help but suffer virtually imperceptible to radical jerks, shifts, and upheavals

Figure 2 The sign or Representamen given three different ways, creating a 'tripodulation.'

along the way. Thus, what she does is processual and ever changing. Everything changes in her semiotic world except change itself. How so?

Unstable Semiotically Engendered Worlds

Figure 2 gives us the sign or Representamen as either (1) a model of the H_2O molecule in a high-school chemistry class, (2) a mannequin in front of a class for the purpose of studying human anatomy, or (3) a dinosaur model before a group of fifth-grade students. The respective objects – and presumably, the means of reference and the referents – of the signs are (1) unempirical in the unaided concrete sense, yet theoretically existent; (2) empirical, and shared by the entire class; and (3) unempirical, and nonexistent in the present, yet theoretically empirical with respect to human observers in the past.

The teacher in each case has the task of rendering the sign meaningful in terms of some referent, whether unseeable without elaborate equipment, evident to the senses, or presumably seeable by some semiotic agent living in the remote past. To complete this task, she must become a sign, because her students interpret her while they interpret her words and her assortment of extralinguistic signs. At the same time, each student and the collective body of students become signs, because she interprets them through the array of nonverbal cues, questions, and comments she receives from them. In this broader, more inclusive sense, the original signs (1), (2), and (3) become semiotic Objects while the teacher and students become Representamens and Interpretants for one another. So we have two tripods, with the inclusion of the sign makers and sign takers. Put in another way, we have a 'tripodulation' of what Donald Davidson (1990) called 'triangulation' in the process of bringing semiotic agents into the equation (Pagin, 2001). The upshot is that reference and referents are of hardly any account if we simply consider meaning to reside exclusively in the word, the sentence, or the entire text. Reference, referents, interpretations, meanings, and understanding are holistic affairs. They require entire contexts. There is no clear-cut demarcation between time and place here. Everything, everywhere, in the past, the present, and the future, to a greater or lesser degree come into play.

This is to say that signs, reference, referents, interpretations, meanings, and understanding, as well as the agents of understanding, are all involved in a coparticipatory process. The participatory semiotic universe entails interdependence, interrelatedness, and interaction in the widest sense. It is much like one of physicist John Archibald Wheeler's examples illustrating his notion of what he calls the 'participatory universe.' Wheeler offered the example of three baseball umpires (1980). One says, "I sees 'em the way they are" (a naive realist or referential causality theorist). Another rebuts, "I says 'em the way I sees 'em" (a perspectivist, who believes sense determines reference). The third umpire, somewhat more cautiously observes, "They ain't nothing 'til I sees 'em" (a process philosopher coparticipating with signs and their meanings). Our third umpire will have no truck with

anything less than the inclusion of herself, ecologically, within the whole of what is becoming (as illustrated in Figure 2). As she becomes, so also everything becomes; everything is always in the process of becoming something other. Indeed, "reference is rather a process than an entity, something that needs to be accomplished every time anew" (Knuuttila, 2003: 109).

Reference is always there, for the making and taking, like all signs. For, the semiotic object, like the semiotic agent herself, is nothing more and nothing less than a sign among signs.

Introduction

The analysis of referring expressions is a major aspect of stylistic analysis because such items determine the way in which entities are described as a story, poem, or play develops, including everything from the major characters to background details. Referring expressions are generally of most stylistic interest when they break the usual patterns in the language, since then they may be used for special effects, for purposes such as highlighting thematic points, creating plot ambiguity, providing a juxtaposition of different perspectives, and representing the style of thinking of characters.

This article examines the stylistic use of reference items from four angles. The first section discusses how theories of mental representation are necessary to explain how readers use their knowledge and make inferences to interpret referring expressions, particularly 'shorthand' forms such as pronouns. The second section examines lexical density, the extent to which referents are referred to by full lexical noun phrases or pronouns, and focuses on cases where there is textual or psychological underspecification. The third section examines how switches between different types of referring expression can create perspective shifts and address shifts. The last section looks at cases of 'displaced' reference, where a writer evades mentioning a referent or refers to something by a seemingly inappropriate designation.

The examples in this article are all taken from narrative texts. Stylistic analyses of referring expressions in poetry and drama can be found in Semino (1997) and Culpeper (2001), respectively.

Knowledge, Inference, and the Interpretation of Reference Items in Texts

A major new area within stylistics is cognitive stylistics, which examines how readers use their knowledge and ability to make inferences to interpret the wording of texts. The interpretation of referring expressions is a key topic of study in cognitive stylistics, as it is in the fields of psychology and artificial intelligence, since 'shorthand' forms such as pronouns provide an indication of how much knowledge a reader needs to bring to a text and what types of processing need to be carried out. This type of approach is radically different from early text models such as Halliday and Hasan's (1976) work on cohesion, which assumed that pronouns were generally interpreted by the reader looking back in the text for an antecedent. Halliday and Hasan's explanation was challenged by Brown and Yule (1983), who argued that if the referent was changing state then an anaphoric search for an antecedent would yield a reference to an out-of-date mental representation of the entity. This places the emphasis on mental modeling rather than simply on what items are present in the text itself. Another challenge to the cohesion approach is the argument that pronouns can be interpreted even when there is no antecedent (see Emmott, 1997, 1999), as shown in Examples (1)–(5) below. These examples demonstrate that different types of knowledge and inference are needed to make sense of the texts. Examples (1) and (2) show the use of schema knowledge (e.g., Schank and Abelson, 1977; see Semino, 1997 for a summary of schema theory and how it has been used in stylistics research). In Example (1), we can infer that if the setting is a hospital, then it is likely to be the medical staff who have washed the patient's hair (although this also requires the assumption that it is the patient who is being discussed here).

(1) Rebus went to the hospital, sat with Rhona. The room, so familiar to him now, was an oasis where calm and order reigned, where each hour of the day brought its comforting rituals.
"**They**'ve washed her hair," he said.
"She's had another scan," Rhona explained.
(Rankin, *The Hanging Garden*, p. 303)

In Example (2) we can again use our schema knowledge to infer that 'they' refers to the builders about to demolish the building, overriding the recent plural noun 'people' which is the only potential human and plural antecedent in the immediately preceding text.

(2) It was as if [Rebus] reached out his hand and plucked possibilities from some tree or bush, expecting people to swallow them. The one time she'd worked with him before – a body found in Queensbury House, just as **they** were readying to knock most of it down [...]
(Rankin, *The Falls*, pp. 312–313)

In addition to schema knowledge, readers need to draw on their text world knowledge (Werth, 1999; see also Emmott, 1997), which is an accumulation of information about the world described by a particular text, including details about the characters, the relations between them, locations in the story, etc. In Example (1), we might guess that 'she' is the patient, but the character can only be fully identified as

the character Samantha if the reader has the text world information that Samantha, daughter of Rebus and Rhona, is the only main female character in this story who is a patient in the hospital. Example (1) sets up a new scene in a previously established location. Alternatively, readers may be required to return to earlier scenes in which events are still ongoing. In Emmott (1997), I provide examples of cases where a reader sets up a 'contextual frame', which comprises knowledge of which characters are together in a particular location at a particular point in time. If the narrative moves on to another frame, then returns to the first frame, it is not necessary to present antecedents for all the characters since the same group can be assumed to still be together. Hence, the 'They' in Example (3) can be interpreted as referring to Jim and Peter, even though only Jim is mentioned. The reader simply needs to recall the earlier scene in which these characters were present in a contextual frame (this 'frame recall' being signaled by the unusually explicit scene indicator 'Housebreaking, Part Two') and make the assumption that Jim is still with Peter.

(3) Housebreaking, Part Two

Jim stopped the car half a block away from the house. "If only the god-damned lights didn't go off." **They** were both looking at the building's blank façade, the curtainless windows behind which no figure moved, no candle shone. (Straub, *Ghost Story*, p. 279)

In the above examples, trigger words, such as the word 'hospital' in Example (1) and the scene indicator in Example (3), provide the means for cueing the relevant text world knowledge. However, in certain cases, a referent is so pervasive in the narrative as a whole that no overt trigger word is necessary (see Wales, 1996: 45 for a similar discussion). In Example (4), the main story up until this point is about the characters' search for a van which they think that their friend Bertie might be able to provide. Although the van has not been mentioned recently, it is still highly salient and when Bertie offers to show them something, the most likely referent is a van.

(4) Bertie opened the gate and nodded at them to get up.
–Come on till I show yis **somethin**'

* * *

It was filthy. He'd never seen anything like it. They walked around it. (Doyle, *The Barrytown Trilogy: The Van*, p. 449)

The pervasiveness of a referent can also be due to the centrality of a particular character in the thoughts of the focalizer. In Example (5), the 'He' mentioned here is not the only male character in the story and there is no trigger phrase to identify the referent, but the focalizing character's obsession with one particular man and her reaction at this point can lead the reader to infer who the male pronoun refers to.

(5) [I] started to walk quickly along Cardamom Street where I could pick up a taxi to the hairdresser's. I stopped dead in my tracks and the world blurred. My stomach gave a lurch. I felt as if I was about to double up.
He was there, a few feet from me. (French, *Killing me Softly*, pp. 19–20)

Stylistic examples of this type challenge traditional anaphoric theory since they show that interpretation of a pronoun is possible without an antecedent and they also raise questions about the distinction between deixis and anaphora (Cornish, 1996; Wales, 1996; Emmott, 1995, 1997, 1999). Examples of interpretable antecedentless pronouns also give an indication of the type of information that needs to be drawn on by readers and hence indicates how schema knowledge and text world knowledge are used while reading a story or other types of text.

Lexical Density and Underspecification

Another major topic in stylistic research on reference is lexical density. Linguists have suggested scales of accessibility (Ariel, 1990) and different degrees of cognitive status (Gundel *et al.*, 1993) to account for the form of a referring expression that is most likely in a particular cognitive environment. Hence, full lexical noun phrases and names are more likely when there are several possible referents or when a referent has not been mentioned for some time. Conversely, pronouns are more likely when a referent has been recently mentioned and when there is no risk of ambiguity.

For special stylistic uses, a writer may sometimes increase the lexical density in a reference chain to achieve special effects, as in the following three examples.

(6) After I'd prepared **our evening meal**, I cooked **our evening meal** and washed up after **our evening meal**. I didn't eat much of **our evening meal** because I was then sick of the sight of it. (Harpwood, *Tea and Tranquillisers: The Diary of a Happy Housewife*, cited and discussed in Ariel, 1990: 200)

(7) [. . .] she'd babbled on and on to **Libby** (it was Aunt **Libby** who had got her through that time, **Libby** with her cool cloths and her aspics, **Libby** who had stayed awake with her all night [. . .], **Libby** who had never left her side, **Libby** who had saved her) [. . .] (Tartt, *The Little Friend*, p. 8)

(8) And **Mother**? Ah. **Mother**.
Mother sang. **Mother** rocked her sometimes, rocked without her sometimes. **Mother** stayed at home with Mozart, swollen as a sow. **Mother** played. **Mother** played. (Galloway, *Clara*, pp. 26–27)

In all these cases, there is no potential for ambiguity, so the repetition is not for the purposes of clarifying which referent is intended. Instead, the repetition serves rhetorical purposes, highlighting a particular entity. The interpretation depends on the context and may be strongly negative, as in Example (6), or strongly positive as in Example (7). The repetition in Example (7) may have some contrastive force, suggesting that Libby performed this role rather than someone else. The word 'Mother' in Example (8) may also be contrastive (e.g., in relation to what the father did) or may emphasize the intense nature of the relationship. Such words can also serve thematic purposes (see Emmott, 2002 for a thematic interpretation of the repeated use of the word 'woman' in D. H. Lawrence's 'The woman who rode away').

At the opposite end of the scale, the lexical density in a reference chain may be decreased, leading to a greater use of pronouns than expected and/or the use of vague lexical terms. Although these forms may be interpretable by the reader using knowledge and inferences (as described in the first section), low lexical density can also lead to underspecification. The term 'underspecification' relates to cases where either the text itself is unclear ('textual underspecification') or a reader's mental representation is unclear (psychological underspecification), or both. Psychological underspecification may result directly from textual ambiguity, but it is also common for a reader's mental representation to be underspecified because he or she has misinterpreted a text or has not engaged with it fully (see Sanford and Sturt, 2002 for a survey of relevant psychological work on shallow depth of processing). Stylisticians are most likely to study cases where psychological underspecification is due to textual underspecification, since in those cases the ambiguous references in the text can be studied using the tools of textual analysis.

Textual underspecification is central to many literary texts since it can facilitate plot twists and convey the confused or limited perspectives of specific characters. One of the most famous examples of ambiguity in literature is Henry James's *The Turn of the Screw*. The whole story is built on ambiguity since the new governess in a household thinks she has been seeing a male ghost, but readers of the story have always been unsure whether they are reading a supernatural tale or a story about a young woman who has an overactive imagination. In the following extract, the use of the textually underspecified 'he' creates confusion in a conversation between the housekeeper, Mrs Grose (who may know more than she admits), and the new governess, the addressee at the beginning of the extract. It is unclear whether the 'he' relates to the master or to someone else, although Mrs Grose's choice of tense ('he *did*,' 'he liked everyone') and her subsequent clumsy late specification of the referent might support the governess's interpretation that it was not really the master whom she was initially referring to. This extract comes from early in the story before the governess's first sighting of the supposed ghost, so at this point the reader and the governess can only feel a sense of unease that all may not be quite as it seems (prompted by several other comments that hint that there is some mystery relating to the previous governess's death). In retrospect, however, we can see the possibility that Mrs Grose might have been referring to the dead Peter Quint, whom the governess now believes to be a ghost.

(9) "The last governess? She was also young and pretty – almost as young and almost as pretty, Miss, even as you."
"Ah then I hope her youth and her beauty helped her," I recollect throwing off. "**He** seems to like us young and pretty!"
"Oh, **he** *did*", Mrs Grose assented: "it was the way **he** liked everyone!" She had no sooner spoken indeed than she caught herself up. "I mean that's ***his*** way – the master's."
I was struck. "But of whom did you speak first?"
She looked blank, but she coloured. "Why of ***him***."
"Of the master?"
"Of who else?"
There was so obviously no-one else that the next moment I had lost my impression of her having accidentally said more than she meant [...] (James, *The Turn of the Screw*, pp. 130–131, James' italics)

In *The Turn of the Screw*, the ambiguity is never resolved and this uncertainty is the whole point of the story. Alternatively, textual underspecification can also lead to garden path effects, where one interpretation of a stretch of text is heavily prompted, then this interpretation is retracted and replaced with another. This happens in Example (10), the context being that just before this passage the main characters, Nazneen and Chanu, have seen the September 11th, 2001 attacks in the United States live on television. In the paragraph immediately before Example (10), Chanu has warned Nazneen of his worries that the attacks might lead to a backlash against the Muslim community. Nazneen then overhears the conversation in the following example in a local shop:

(10) Four men leaned over the counter, studying a paper so closely that when they looked up she almost expected their eyeballs to be smudged with newsprint.
"**It's** very serious," said the eldest [...] (Ali, *Brick Lane*, p. 368)

At first Nazneen thinks that her husband should be there to discuss the world events with these men, since he has been heavily affected by the September 11th attacks. Suddenly, however, she realizes that the 'It' refers not to the situation following the September 11th attacks, but to a local strike of garbage disposal workers. The double-take of both the character and, in consequence, the likely double-take of the reader provide an ironic perspective on the gap between Nazneen and these men in the local community, and also offer a comment on the fact that the frustrations of everyday life continue even in the wake of such major world events.

Within stylistic studies, many of the classic examples of textual underspecification are cases where a particular 'mind-style' (Fowler, 1986/1996) is presented, reflecting limits in the perception of characters due to such factors as young age, madness, limited mental capacity (Leech and Short, 1981), and the viewpoint of Neanderthal man (Halliday, 1971). Often such texts provide vague descriptions that do not immediately identify referents fully, reflecting the failure of the characters to comprehend what they are perceiving. Nevertheless, there are often sufficient clues in the text for a reader to be able to draw on his or her schema knowledge to identify a particular situation or activity and thereby to appreciate what it is that these characters are failing to understand (see Bransford and Johnson, 1972 for psychological work on these types of underspecified texts). Hence, a reader can build an adequately specified mental representation of the scene, albeit one that might take rather longer to construct than usual. Example (11) provides an illustration of this type of textual underspecification in which Monica Ali uses a vague description to reflect the mind-style of Nazneen, who has recently arrived in London from Bangladesh for an arranged marriage. Nazneen is watching television, but lacks the relevant schema knowledge and she does not speak sufficient English to understand the television commentary.

(11) **A man in a very tight suit (so tight that it made his private parts stand out on display)** and **a woman in a skirt that did not even cover her bottom** gripped each other as an invisible force hurtled them across an oval arena. [...] The couple broke apart. They fled from each other and no sooner had they fled than they sought each other out. Every move they made was urgent, intense, a declaration. The woman raised one leg and rested her boot (Nazneen saw the thin blade for the first time) on the other thigh [...] (Ali, *Brick Lane*, p. 36)

The mention of the boot with the thin blade is presumably sufficient to indicate to the reader that Nazneen is watching an ice skating programme (if the reader has not already guessed this) and her husband shortly afterwards confirms this by teaching her the English words 'ice skating.' The ice skating is crucial to the story because it not only shows Nazneen's mind-style at this early stage in her marriage, but because ice skating then runs as a theme throughout the book. Ice skating provides an example of the glamor that is lacking in Nazneen's marriage, but also, at the very end of the story, as Nazneen herself skates in her sari at a local ice-rink, provides a symbol for the extent to which she has integrated into Western society and yet still retains her cultural identity.

A similar type of effect is created in the same book in the following underspecified description, which requires readers to draw on their knowledge of world events to interpret the scene.

(12) "Oh God," Chanu says. "The world has gone mad."
Nazneen glances over at the screen. The television shows **a tall building** against a blue sky [...] A thick bundle of black smoke is hanging outside **the tower**. It looks too heavy to hang there. An aeroplane comes in slow motion from the corner of the screen. It appears to be flying at the level of **the buildings**. Nazneen thinks she had better get on with her work.
"Oh God," shouts Chanu. [...]
The scene plays over. [...] The aeroplane comes again. The television shows it again and again. [...]
The scene switches. "The Pentagon," says Chanu. "Do you know what it is? It's the *Pentagon*."
The plane comes again and again. (Ali, *Brick Lane*, pp. 365–366, Ali's italics)

Although it is not explicitly stated, most readers will presumably be able to identify the first scene as the attacks on the twin towers of the World Trade Center, even before the mention of the Pentagon makes it clear that this is a description of the September 11th attacks. Our schema knowledge can enable us to identify the references to the buildings and can also clarify the description of the events, which blurs what actually happened with the repeated replays on television. Again, Nazneen's failure to understand the English television commentary makes her dependent on her husband to explain the significance of what she is perceiving.

Underspecification can also be used to create a sense of suspense and/or drama when introducing a major participant at a key moment in the plot.

The underspecification can capture our attention and lead us initially to wonder who is being referred to before gradually disclosing the identity of the individual, as in the following example.

(13) Then **someone** walked in. **Someone Rebus knew**. **Dr Colquhoun** (Rankin, *The Hanging Garden*, p. 231)

This is quite different from the use of indefinite pronouns to refer to a participant who is so minor that they do not need to be identified, as in the example below:

(14) The news conference took place at the Big House, with a live feed to the inquiry room at Gayfield Square. **Someone** was trying to clean fingerprints and smears from the TV monitor with a handkerchief, while others tilted the blinds against the afternoon's sudden burst of sunshine. (Rankin, *The Falls*, p. 43)

The difference here seems to be due to the fact that in Example (13) the text combines underspecification with an indication that the identity of the referent is significant (due to the repetition and the fact that we are told that it is 'Someone Rebus knew'), whereas in Example (14) the 'Someone' appears to be simply an incidental participant in the context (a 'scenario-dependent character' in Sanford and Garrod's [1981] terms).

At moments of high drama, the technique of gradual disclosure can be accompanied by the shocked reaction of the characters, which highlights the fact that the unidentified entity is of particular significance, as in the appearance of the shark in the example from *Jaws* below:

(15) **Something** caught his eye and made him turn to the left. **What he saw** sucked from him a throaty grunt [. . .]
"Jesus Christ!" said Brody.
No more than ten feet off the stern, slightly to the starboard, was **the flat conical snout of the fish**. (Benchley, *Jaws*, p. 233)

As in Example (13), the way in which the text lingers on the unidentified entity in Example (15) ('Something caught his eye,' 'What he saw') draws the reader's attention toward it. The pseudo-clefting in 'What he saw . . .' also adds linguistic emphasis. In cases of this type, graphical features such as italics, sentence fragmentation and unusual paragraph indentations can provide signals that may attract the reader's attention toward the indefinite reference and highlight its significance (see Emmott *et al.*, 2003 for a stylistic discussion of examples with graphical highlighting).

Referential Shifts: Changes in Perspective and Terms of Address

Referential shifts allow changes in perspective, which can be of key stylistic importance in many literary texts. Within narratology, there has been particular interest in switches from main narrative into the thoughts of the characters (e.g., Leech and Short, 1981; Fludernik, 1993; Bal, 1997; Toolan, 2001). In streams of consciousness fiction, third and first person pronouns can alternate as the narrative levels switch between an omniscient narrator describing a character and the internal focalization of that character. The following examples from Joyce's *Ulysses* illustrate this type of switch in relation to Stephen Dedalus's and Leopold Bloom's thoughts, respectively. In each case, the third person pronouns and first person pronouns are coreferential.

(16a) **He** halted. **I** have passed the way to aunt Sara's. Am **I** not going there? Seems not. (p. 46)

(16b) On the doorstep **he** felt in his hip pocket for the latchkey. Not there. In the trousers **I** left off. Must get it. (p. 59) (Both examples from Joyce, *Ulysses*)

This type of juxtaposition can lead to a clash of different views. In the example below, the text contrasts Nazneen's brutally honest assessment of a situation with the initial more neutral view.

(17) **They** had never, in all those years, been invited back. And **we** were never invited in the first place, Nazneen reminded herself. (Ali, *Brick Lane*, p. 245)

Immediately preceding this quotation, Nazneen's husband, Chanu, has spoken of an earlier incident in the novel when he and Nazneen visited Dr. Azad's house, without indicating that they arrived uninvited. The initial statement of Example (17) also fails to acknowledge this fact, but the switch into the first person shows the double-take of Nazneen as she challenges the presupposition of the previous sentence.

For linguists, there is particular interest in reference shifts where the shifts break the usual expectations of traditional grammars. This applies to switches from definite to indefinite, since we would normally expect references to remain definite once definiteness has been established. Du Bois (1980) provides a classic analysis of this issue in relation to the famous *Pear Stories* film, showing that late indefinite references to the central boy in the film are due to perspective shifts (see also Sanders, 1994). Hence the sense of indefiniteness can be attributed to the focalizing character's knowledge state, not the reader's knowledge state. These perspective shifts can be of different types. In

Example (18), the identity of 'a girl' is unknown to the focalizing character, Stella, but the reader has ample background knowledge to infer that this must be a character who has appeared in the previous chapter.

(18) [Stella] came face to face with **a girl** standing uncertainly on the threshold. In one hand she carried a steaming saucepan, from which protruded the top of a feeding bottle. Her face appeared to be exceedingly dirty, and she carried her other arm in a sling. (Mitchell, *The Token*, p. 62)

Sanders (1994: 97–99) provides a subtly different example (from a Dutch translation of the story about Ruth in the Bible) in which the indefiniteness is probably due to a temporary lack of recognition since a character has fallen asleep and awakened to find 'a woman,' whom he supposedly knows, lying there. Example (19) below is rather different since both the reader and Mark must know that 'a woman' denotes Martha, for Mark has gone to her room with the intention of speaking to her.

(19) Mark made a visit to Martha's room [. . .]
"Do you mind if I come in?" He switched on the light [and as he did so he remembered all the previous times he has entered this room, going back to his childhood in the house].
He took hold of the present, where **a woman in a red housecoat, with untidy hair**, sat by a dark window [. . .] (Lessing, *The Four-Gated City*, pp. 202–203)

Here the indefiniteness provides a sense of distance in the relationship between characters, a technique used repeatedly in the novel to give a defamiliarizing effect (Shklovsky, 1965) to the scene.

In addition to these perspective changes, shifts in terms of address can signal changes in the social relations between characters. A considerable amount of work on this topic has been done by stylisticians working on drama texts, since address is of obvious significance in the dialogue medium of drama. Culpeper (2001: 193–199) summarizes work in the field, looking particularly at the switches in 'you' forms and 'thou' forms in Shakespeare's plays (drawing on Brown and Gilman's [1960] theoretical framework), arguing that they can have social and pragmatic significance, including indicating positive or negative emotions at specific points in a play.

Terms of address forms can also be significant in narrative, as in the following example in which the thoughts of Nazneen (in italics) filter into the direct speech of her husband Chanu to challenge his recollection of earlier events.

(20) '[Chanu] raised a finger and his voice. ''But **Azad** said, not in so many words, that I had done something underhand. I told him, 'Look **Azad** *(I was there! Don't you remember? I was there, and you always call him* ***Dr****)*, I asked you to sign my petition [. . .]'. . . .]" (Ali, *Brick Lane*, p. 75, Ali's italics)

Second person pronouns have attracted a great deal of interest in narratology (e.g., Bal, 1997; Fludernik, 1995, 1996, 1998), since they challenge the traditional notion of the narrator and seem likely to intensify the involvement of the reader. The following examples show second person narration which, in the full text, is interspersed between first person narration.

(21a) If **you** did something once when you were twenty, and if **you** realized at that moment that it was the happiest moment of **your** life, then that in itself is a crushing thought to have. **You** will never be happier. (p. 2)

(21b) Evelyn Cotton is my heroine. If **you** were living in this world, she might be **yours**. As it is, **you** have only read her books and seen her on **your** television. **You**, as the public, love her or hate her. (p. 2)

(21c) In the mean time **you** are married. **You** have children and **you** make money. For twenty-three years, each time **you** penetrate your wife **you** are trying to recall that once with Evelyn Cotton. Each of **your** children was conceived while **you** thought about Evelyn Cotton [. . .] (p. 2)

(21d) Now, her arms and legs are wrapped around **you**. Her belly slides softly across **yours**, trapping small bubbles of air between them. Her chin is dug into **your** clavicle. The rhythms of her voice that used to haunt **you** every night are rushing past **your** ear [. . .] (p. 22) (All examples from Ronan, *The Men who Loved Evelyn Cotton*)

In Example (21a), the narrator, having described an affair in his youth in the first person, switches to what seems to be a generic 'you' form. In Example (21b), the possibility of the generic 'you' entering this text world is discussed and the fictional Evelyn Cotton is assumed to have a status in the addressee's own world. In Example (21c), there is a stronger identification between the narrator and the supposed addressee with events in the narrator's life being attributed to the addressee (although this may still be hypothetical, covered by the 'if' of Example (21a) that precedes this example). In (21d), an extract that is preceded by both I-narration and also you-narration of the types shown in Examples (21a) and (21c), the addressee is suddenly placed directly in the love-making scene with Evelyn Cotton, hence challenging the usual separation of the worlds of the characters and the reader suggested by text world theorists such as Werth (1999).

Referential Displacement

Transitivity Analysis

Stylisticians have made extensive use of models of transitivity from mainstream linguistics in their studies of referring expressions in texts, particularly using Halliday's work (e.g., Halliday and Matthiessen, 2004). Many stylistic studies have shown how agency can be displaced, drawing attention away from the role of a particular referent in a sequence of events in order to show how a character fails to understand the agency underlying events (often in the representation of a restricted mind-style) or how responsibility is evaded by a character (e.g., Halliday, 1971; Leech and Short, 1981). Examples (22a) and (22b) demonstrate this type of displacement at a plot-central moment in the story. Here, years after the events being described, the I-narrator confesses for the first time her role as murderer of the two women, Karen and Anethe. The text does not explicitly state that the I-narrator hits these women with the chair and axe, respectively, but clearly if the I-narrator is holding the chair and the axe in each case and we are then presented with the specified consequences, we can assume that she is responsible. Although agency can be inferred, the fact that it is not openly stated can be taken to reflect the mind-style of the protagonist, reflecting her refusal to come to terms fully with her actions in spite of her confession.

(22a) [I] gripped that chair-back so hard my knuckles whitened.
Karen staggered two or three steps under **the blows from the chair** and, twisting around, turned towards me [...] A small exclamation escaped me, as I stood there with the chair in my hands. (pp. 233–234)

(22b) [...] I did extend my hand, but I did not reach [Anethe]. She did not move, and neither then could I.
It is a vision I have long tried to erase, **the axe in the air**. Also as well the sight of blood soaking the nightgown and the snow. (p. 235) (Both examples from Shreve, *The Weight of Water*)

Physical and/or mental incapacity can also be signaled by displacing agency. In the following example, the displacement reflects the false perspective of the drunk focalizer, for it is his perception that is affected, not the room that is moving.

(23) **The room** began to rise upwards from the right-hand bottom corner of the bed [...] He threw back the covers and sat on the edge of the bed, his legs hanging. **The room** composed itself to rest. After a few moments he swung his legs back and lay down. **The room** lifted. (Amis, *Lucky Jim*, p. 61)

In the above examples, agency is elided for major stylistic reasons, but the same type of effect can also be achieved for reasons of economy of presentation in relation to minor descriptive details, as shown in the two examples below:

(24a) Here came **the scallop shells** [...] (Lessing, *The Four-Gated City*, p. 38)

(24b) **The brandy** he had ordered arrived. (Rendell, *Going Wrong*, p. 172)

Here readers need to use their restaurant schema knowledge (Schank and Abelson, 1977) to override the literal meaning of the statements and attribute agency to a waiter rather than to the food and drink. These examples are of less stylistic interest than Examples (22a) and (22b), but Examples (24a) and (24b) nevertheless show how references to the actions of minor characters can be attenuated in order to put the main emphasis on the major characters in the story.

Mental Spaces

Another type of displaced reference has been identified by Fauconnier (1994) in his mental space theory. This work shows how a reference item may be used that, if read literally, could be seen as inappropriate. However, in context, the reference item can be used for economy of presentation and/or special stylistic effect.

In Example (25), the Questioner uses a classic type of metonymy, referring to the images of the children directly by the names of the children. When Nazneen holds the pictures, the names represent the photographs as physical objects and the usage is arguably a little more unusual. The stylistic effect of the metonymy is to increase the sense of Nazneen's empathy with the children.

(25) The Questioner held up another photograph. "Some more Iraqi children. Mashgal, Adras and Misal. All under one year [...]"
Nazneen relinquished **Nassar** and she held **Mashgal, Adras and Misal**. (Ali, *Brick Lane*, p. 282)

The following example is much more unusual and hence might be perceived as highly marked stylistically. In this case, the reference to Nazneen's sister refers to a letter the sister has written. Due to Nazneen's enforced move to Britain, the letter is the only contact that Nazneen has or is likely to have with her sister. Hence the letter is symbolic of the way that the sister's correspondence has taken over the role of the sister herself.

(26) Nazneen went into the bedroom and, from the modest seclusion of the underwear drawer, unveiled **her sister**. (Ali, *Brick Lane*, p. 265)

Example (27) shows another classic type of displaced reference across temporarily distinct mental spaces. In such cases, a narrator's perspective can lead to the use of a designation that postdates the events being described, in this case because the narrator is referring to her mother as a child, hence before she was a mother.

(27) **My mother** and her younger sister would loiter near the closed office door until shooed away. (Atwood, *Significant moments in the life of my mother*, p. 12)

The same type of apparent inappropriateness of designation is seen in Example (28), where a narrator recreates events that previously occurred in the life of the dead owner of the narrator's mountaineering ice-axe. If we were to take the text literally, then clearly the animacy of the dead man would be nonsensical, but this is nevertheless a common way of seeing the events from the perspective of the current narrator, for whom 'the dead man' is the most appropriate designation.

(28) They were all merry, and **the dead man** particularly so, when they left the pub and headed for the bus [...]

They went upstairs in the bus – for **the dead man** smoked heavily [...]

The dead man was a gangster, in double-breasted suit and Homburg hat which suited his rascality. He was ill [...] (Mitchell, *Dead man's ice-axe*, pp. 66–67)

More stylistically unusual are the following passages from a different story by the same author. In this case, the focalizing characters suddenly realize that a man who had been assumed to be dead is actually alive.

(29) [They] looked at **the body** which lay amidst the piles of equipment and cans. At **the corpse** whose eyes were open, blinking, and whose breathing could be discerned at its throat. Neither of the two spoke, but waited for **the dead man** to do so. (Mitchell, *A friend of the family*, p. 40)

In Examples (29) and (30), the reference items become incongruous as 'the dead man' opens his eyes and begins to speak:

(30) "You were in a coma. We think you had an attack of oedema at altitude. He brought you down, saved your life. [...]"

She distanced herself from the other, leaving him to explain to her husband what had happened.

"Did you get to the top?" continued **the corpse**. "Yes? Good man!" (Mitchell, *A friend of the family*, p. 40)

The continued references to the character being dead reflect how the two observing characters, the 'dead man's wife and his climbing partner, struggle to readjust their perception of the situation. The referring expressions are also deeply ironic since this episode follows on immediately after a discussion in which the wife takes the opportunity of her widowed status to proposition the climbing partner and suggest that he steps into the 'dead man's shoes.

The above examples show the range of uses of displaced references, from everyday economy of expression to heavily plot-significant items. Within cognitive linguistics, detailed examination of this type of phenomenon has been carried out in relation to narrative texts by Sanders (1994), Oakley (1998), and Dancygier (2005) using Fauconnier's mental space theory and the more recent blending theory of Fauconnier and Turner (2002).

Conclusion

Although not exhaustive, the above discussion summarizes some of the major issues in the stylistic study of reference. The main emphasis in stylistics has generally been on the form of referring expressions, particularly where there are shifts in use throughout a text (as described in the last three sections). The knowledge and inferences needed to interpret referring expressions have also received particular attention in recent years, as part of the mental modeling approach within cognitive stylistics (as discussed in the first section).

Acknowledgments

Some of the research in this article was conducted as part of the LINCS Project (*Literature, narrative and cognitive science*) and the STACS Project (*Stylistics, text analysis and cognitive science*) and was funded by two Arts and Humanities Research Board grants (Innovation Award B/IA/AN8799/APN13740 and Research Grant B/RG/AN8799/APN19525), in addition to British Academy grant 32623. I am grateful to these organizations for their support and also to my colleagues on these projects, Anthony J. Sanford and Lorna I. Morrow, for allowing me to use material collected for our joint research (Examples [1], [2], [13], [14], and [15]). I am also grateful to Christian J. Kay who allowed me to use Example (23) from her teaching materials on transitivity.

Referential Relations in Spoken Discourse

The Problem of Anaphoric Distribution in Discourse

The term 'reference' refers to the relation existing between a sign and an entity in the world. An act of reference is the activation of a textual referent within discourse, that is, the evocation of an entity in the world through a linguistic expression within discourse.

All languages have lexical, morphosyntactic, and prosodic means to refer to entities in the world and to signal the relations existing between referential expressions within discourse. At least two prototypical categories of referential expressions can be identified: descriptors, i.e., forms with autonomous semantic content that allow for the representation of their referents; indexical expressions, i.e., forms without autonomous semantic content that function as instructions for the singling out of referents in the discourse model. In oral discourse, indexical expressions can belong to either the linguistic level – pronouns, inflectional morphemes – or the paralinguistic level – hand/head/eye movements. The latter have not yet been the subject of comprehensive studies, but future research will undoubtedly confirm their importance. For example, Ozyurek (2000) shows that speakers in a group codify space so as to contrast the space internal to the group – which refers to entities and information belonging to shared knowledge – with the space external to the group – which refers to nonshared knowledge. In other words, it is possible to create spatial file labels to which one can refer by modifying the direction of one's gestures and eye or head movements. An analogous phenomenon is found in signed languages, where the direction of one's movements is used to identify the referents of anaphoric and deictic expressions (Metzger and Bahan, 2001).

Both the speaker's choice of referential expressions and their interpretation on the part of the addressee are subject to morphosyntactic, semantic, and pragmatic constraints that vary across languages and may differ in their strength. In the case of oral discourse, we will discuss here what Huang calls "the problem of anaphoric distribution in discourse," that is "how to account for the choice of a particular referential/anaphoric form at a particular point in discourse" (Huang, 2000: 302).

The Problem of Anaphoric Distribution in Discourse

The term 'reference' refers to the relation existing between a sign and an entity in the world. An act of reference is the activation of a textual referent within discourse, that is, the evocation of an entity in the world through a linguistic expression within discourse.

All languages have lexical, morphosyntactic, and prosodic means to refer to entities in the world and to signal the relations existing between referential expressions within discourse. At least two prototypical categories of referential expressions can be identified: descriptors, i.e., forms with autonomous semantic content that allow for the representation of their referents; indexical expressions, i.e., forms without autonomous semantic content that function as instructions for the singling out of referents in the discourse model. In oral discourse, indexical expressions can belong to either the linguistic level – pronouns, inflectional morphemes – or the paralinguistic level – hand/head/eye movements. The latter have not yet been the subject of comprehensive studies, but future research will undoubtedly confirm their importance. For example, Ozyurek (2000) shows that speakers in a group codify space so as to contrast the space internal to the group – which refers to entities and information belonging to shared knowledge – with the space external to the group – which refers to nonshared knowledge. In other words, it is possible to create spatial file labels to which one can refer by modifying the direction of one's gestures and eye or head movements. An analogous phenomenon is found in signed languages, where the direction of one's movements is used to identify the referents of anaphoric and deictic expressions (Metzger and Bahan, 2001).

Both the speaker's choice of referential expressions and their interpretation on the part of the addressee are subject to morphosyntactic, semantic, and pragmatic constraints that vary across languages and may differ in their strength. In the case of oral discourse, we will discuss here what Huang calls "the problem of anaphoric distribution in discourse," that is "how to account for the choice of a particular referential/anaphoric form at a particular point in discourse" (Huang, 2000: 302).

Cognitive Approaches: Referring as an Identifying Strategy

The best-known linguistic/philosophical and cognitive studies into how referential relations are expressed (see Reinhart, 1983; Givon, 1990; Huang, 2000) rest on the following assumptions:

1. The primary communicative aim underlying the use of linguistic expressions is that of transferring information, i.e., increasing the amount of shared knowledge.
2. Referential expressions function as file labels under which information is stored. In other words, they function as shared starting points for building up discourse.
3. All information is understood against the background of the context shared by the speech participants (Olson, 1970). Such a context, in the case of spoken discourse, includes:
   a. general and individual knowledge;
   b. the concrete situation in which discourse takes place;
   c. a mental image of the ongoing discourse (or discourse model), which is made up of the inferences, presuppositions, and implicatures generated by discourse.

Each speaker's amount of knowledge is not stable but changes as discourse proceeds. Further, at any instant, some piece of knowledge can be the object of discourse while other pieces of knowledge may remain in the background and not be brought up for discussion. At any single time t_n of discourse, a piece of knowledge in each speaker's discourse model can be (see Levelt, 1989; Lambrecht, 1994; Gundel *et al.*, 1993 for related scales concerning the degree of activation and identifiability of referents):

1. accessible or inaccessible (i.e., stored or not stored);
2. active or inactive (i.e., present in or absent from the speech participant's state of attention at time t_n);
3. focused (i.e., whether it is the object of discussion at time t_n or not).

The discourse model, including stored knowledge and its degree of activation at a given time, is not exactly the same for different speech participants. In other words, speech participant p_a's discourse model and its representation by a different speech participant p_b may not coincide. Consequently, any piece of knowledge related to discourse can:

1. be regarded as being shared or not shared;
2. actually be shared or not shared.

For any transfer of information to be successful, the addressee needs, as a consequence of the speaker's utterance, to integrate the information found in the utterance into her discourse model according to the speaker's intentions. The speaker should therefore select referential expressions so as to allow the addressee to identify their referents and link them to the relevant pieces of contextual information. In particular, the use of referential expressions should be conducive to signaling the degree of accessibility and activation of their textual referents within the ongoing discourse so that the addressee can recover their referents from her own discourse model.

Differences among cognitive models primarily involve the identification of the parameters deemed necessary to define the accessibility and degree of activation of referents at a given time in discourse. In Givón's model (1983, 1990), the study of referential expressions is linked to the notion of topicality, which had already been a feature of Prague School functionalism and is now reformulated in cognitive terms (Givón, 1990). Thanks to numerous typological and interlinguistic studies focusing, in particular, on narrative texts (both oral and written), a great many parameters have been identified that allow us to measure the accessibility and relevance of a topical referent. These parameters can be syntactic (e.g., the subject role), semantic (e.g., animacy, agentivity, definiteness), textual (e.g., the protagonist role, knowledge shared between participants, recurrent and/or recent mentioning, absence of competing referential values, referential continuity). The resulting model for the use of referential devices is basically an iconic one (Figure 1).

Based on similar premises is Klein and von Stutterheim's model (1987), which was integrated with Quaestio theory and used in the ESF project (see Perdue, 1993) to describe how referential movement, especially in narratives, is built in language learners' varieties.

The diagram in Figure 1 applies to both oral and written discourse. However, oral and written discourse

Figure 1 Accessibility, activation, and referential means.

can use different means to signal the information status of referents. Alternatively, they can make use of the same devices, albeit with differences in frequency. Givón (1983) identifies as typical features of oral discourse the use of dislocation and that of presentative structures.

Nonactive referents are activated in discourse by way of 'heavy' devices, such as descriptors and morphosyntactic strategies suited to introducing nonidentifiable or nonactive referents. Once activated, the textual referent functions as a file label and can be retrieved subsequently from the discourse model through 'light' referential means. In the following example (Givón, 1983), the referent *Frenchman* is introduced through the presentative structure *there was a* . . . as well as a descriptor. Later on, it is retrieved through the pronoun *he*. Specifiers help to signal the degree of identifiability and activation: example (1) illustrates the use of the demonstrative determiner to signal referential identifiability (*these big ranchers*, *this BLM land*). This device is very common in spoken language, where the signaling of referential status seems to be usually emphasized.

(1) [a man telling the story of his family as they arrived in New Mexico]
And my dad did lease some, ah, 'course BLM had land and they had it all leased to these big ranchers. And there was a Frenchman up south of Grants, ol' Juan Yarty. He had worlds of sheep. And he had all this BLM land that was around us down here . . . and he raised sheep, you know

Referents available in the shared spatiotemporal environment will be activated in discourse through light referential devices, ellipses, or linguistic or paralinguistic deictic indexes, possibly in conjunction with definite descriptions. Similarly, in order to refer to the speaker and addressee, specific indexical expressions will be used, namely the first person and second person pronouns:

(2) [conversation on how to do the washing, from the LIP corpus (LIP, 1993)]

C:	Questo	blu	Filippo	tu	questo	come
	this	blue	Filippo	2sing	this	how
	lo	mett-i	nell'	acqua	basta	
	it	put-2sing	in the	water	that's it	

'This blue one, Filippo, what would you do with you? Would you just put it into the water?'

(3) [on the bus]

B:	Scend-i	alla	prossima?
	get off-2sing	at the	next

'Are you getting off at the next (stop)?'

(4) [conversation between two colleagues, A and B; colleague C walks past them as the conversation unfolds]

A:	Dev-o	ancora	sempre	parlar-gli
	Must-1sing	still	always	talk-(to)him

[nodding in the direction of C]
'I haven't talked to him yet'

Referents that are assumed to be accessible on the basis of the knowledge shared by the speech participants can be activated by using light referential devices:

(5) [two acquaintances, a few days after President Kennedy's assassination, quoted in Schlegoff, 1996: 451]
Is he still alive?

(6) [student A to his flatmate B as the latter comes back from an exam that A was aware of]
A: How did it go?

Similar premises are also Sacks and Schlegoff's (1979) starting point. They claim that the use of referential expressions in interactions result from two simultaneously operating principles:

1. the principle of expressive minimization
2. the principle of referential identification

In other words, the speaker should use the most economical expression that allows the hearer to identify a referent. The novelty of Sacks and Schlegoff's study lies above all in the texts they chose to analyze. They focused on dialogic conversation within the conversation analysis model. Dialogic conversation shows how strategies mediating between the two principles work as the conversation unfolds (*Survey of English usage*, cited in Huang, 2000: 321):

(7) 1. B: and he said well I'm sorry ((you know)) we don't' cater for this you'll just have to change you timetable
2. or work at home ((so)) I said this just means I shall do half as much work # ((and)) he/ said 'very well #
3. A: /[k] 'who said 'this#
4. B: the/secretary#*.*of the/'school#
5. A: */'m#*/ who's 'that@
6. B: /George 'Fornby#

Recipient A's failure to recognize the intended referent (see line 3 and, later on, line 5) triggers interactional repair mechanisms. Speaker B's need to guarantee the referent's identifiability forces him to progressively resort to less economical expressions (see lines 4 and 6).

Conversation Analysis Approaches: Referring as a Communicative Move

A few studies underline the need to combine the iconic model with the view of texts as hierarchically structured entities, especially with respect to the notion of continuity. In other words, continuity and discontinuity should not simply be evaluated in relation to the linearity of a text but, rather, with respect to its structure. Heavy linguistic devices are claimed to be typically used for referential purposes at the beginning of a new chunk of text ('locally initial' reference according to Schlegoff, 1996). Light linguistic devices are used for referential purposes within a chunk of text ('locally subsequent' reference according to Schlegoff, 1996). This suggestion, which has been developed within the conversation analysis model, has in part validated the iconic model. Light forms turn out to be used within adjacency pairs and in sequences of related adjacency pairs as 'series' or 'postelaborations' (see Sacks and Schlegoff, 1979; Fox, 1987; Schlegoff, 1996).

However, the choice of referential expressions itself contributes to the structuring of discourse, which, in keeping with the conversation analysis model, is not viewed as having been fixed in advance but rather as being coconstructed by the speech participants (discourse structure is not objective but reflexive in Schlegoff's [1996] opinion). A heavy device can be used for a linearly close and active referent in order to signal the end of a sequence or the opening of a new one (Schlegoff, 1996: 452).

(8) 1. Mark: So (') you da:ting Keith?
2. (1.0)
3. Karen: 'Sa friend.
4. (0.5)
5. Mark: What about that girl 'e use tuh go with fer so long.
6. Karen: A:lice? I [don't-] they gave up.
7. Mark: [(mm)]
8. (0.4)
9. Mark: (°Oh?)
10. Karen: I dunno where she is but I-
11. (0.9)
12. Karen: Talks about 'er evry so o:ften, but-I dunno where she is.
13. (0.5)
14. Mark: hmh
15. (0.2)
16. Sheri: Alice was stra::nge,
17. (0.3) ((rubbing sound))
18. Mark: Very o:dd. She usetuh call herself a pro:stitute, ='n I useteh-(0.4) ask 'er if she wz gitting
19. any more money than I: was.

In (8), Sheri's use of the NP *Alice* (line 16) to refer to an active referent that has just been mentioned signals her intention to open a new communicative sequence (of a narrative type) where such a referent is construed as a topic, after Mark's similar attempt (which began in 5) was repeatedly rejected by Karen (lines 6, 10, 12) (see Schlegoff, 1996: 452).

Conversely, light forms can also be used in sequences where a turn is not linked to immediately adjacent turns but rather to previous turns so as to reopen a communicative move (Fox, 1987: 30):

(9) 1. A. Oh my mother wannduh know how's yer grandmother.
2. B. hhh Uh:: (0.3) I don'know I guess she's aw-she's awright she went to the uh:: hhospital again tihda:y,
3. A. Mm-hm?
4. B. hh t! hh A:n:: I guess t'day wz d'day she's supposetuh find out if she goes *i*n ner or not.=
5. A. =Oh. Oh::.
6. B. Becuz they're gonna do the operation on the teeuth duct.
7. -f//fi:rs]t. Before they c'n do t//he cataracts.
8. A. Mm-mh,
9. A. Right.
10. A. Yeah,
11. B. hhh So I don'know I haven:'t yihknow, she wasn' home by the t-yihknow when I left'fer school tihday.=
12. A. =Mm hm,
13. B. Tch! hh So uh I don't kno:w,
14. (0.3)
15. B. En:=
16. A. =°M//hm
17. B. Well my aunt went with her anyway this time,
18. A. Mm hm,
[
19. B. My mother didn't go.
20. A. Mm hm,
21. B. t! hhh But uh? I don'know = She probably haf to go in soo :n though.

In the sequence in (9), *she*, in line 21, is to be linked to *grandmother*, which was introduced in line 1. The return pop is signaled, alongside the use of the pronoun, by combined strategies such as the repetition of lexical material from the turn we are being linked to (between lines 4 and 21) and is repeatedly announced by the repetition *I don't know*. Referring takes place thanks to a light form despite the presence of competing referents that are linearly closer (i.e., *my mother*, line 19; *my aunt*, line 17). The use of a light form in line 21 allows the turn to be tightly linked to the turn in lines 2–4 as an elaboration of the latter (being

Figure 2 Structure of return pop (ex. 9).

the answer to the question in line 1). The sequence in (9) has therefore the structure shown in Figure 2.

Fox (1987) has also pointed out the existence of some correlations between the choice of referential expressions and communicative moves. A referential expression is typically repeated in order to restart, to repair an overlap, or to make an other- or self-correction, possibly functioning as an objection and signaling disagreement (Jones and Beach, 1994, quoted in Schlegoff, 1996: 444):

(10) 1. Therapist: I see so they remember that you flunked first grade and even though you're in third grade they call you a flunking first grader?
2. Son: But I don't flunk I didn't flunk Mom didn't want me to pass cause I missed too much school
3. Therapist: Oh she [wanted you to make=
4. Son: [Right
5. Mother: =No::
6. Son: .hh But y[ou didn't [
7. Mother : [Mom [Mom made a trade with the school if they would . . .

In (10), the speaker of line 7 designates herself as *Mom* to signal disagreement with what was said in line 2. The repetition of the full NP is here an instance of a typical procedure by which one's own disagreement is pointed out.

Phenomena that may turn out to be problematic if only the notion of referential continuity is invoked can also be explained as communicative moves. They include the repetition of a full NP referent in topic position in Chinese question/answer pairs (Huang, 2000: 307):

(11)

C1.	A:	Na	ta	fuqin	gan
		uhm	3sing	father	do
		shenme	ne		
		what	Q		
C2.	B:	Ta	fuqin	zai	daxue
		3sing	father	in	university
		li	jiaoshu		
		LOC	teach		
C3.		Ø	jiao	guwen	
			teach	Classical Chinese	

'A: Uhm what is his father doing'
'B: His father teaches in a university. (He) lectures on Classical Chinese'

The repetition of the topic in (11), which is unwarranted in terms of activation and identification needs, corresponds to a move of acceptance of the topic on the part of the addressee.

Socioethnographic Approaches: Referring and 'Other Activities'

Socioethnographic studies of referential expressions within a Gumperzian and Goffmanian framework have shown that the selection of referring devices is linked, among other things, to strategies that define, signal, and manage the social identities brought into the interaction by the participants, as well as being related to the participants' attitude toward each other, the ongoing discourse and the mentioned referents.

This point had already been made by Schlegoff (1972: 81) and observations along these lines can also be found in the studies mentioned so far. Schlegoff (1996) observes that in service encounters the opposition between singular and plural in the first and second persons signals whether speaker and addressee are referred to as individuals or stand for institutions, respectively (see *Calls to an emergency hot line*, Whalen and Zimmerman, 1990):

(12) Caller: uh: this iz uh:da g .h Knightsuv Columbus Hall. . .
.hh we had some uh women's purses uh stolen. . .

(13) Caller: Yes sit uh I go' a couple guy:s over here ma:n they thin bunch uh wi:se

Such an alternation has an identifying function not with respect to the referent's identity but rather in relation to his or her social role in the interaction.

It has also been observed that person alternations are related to an increase in involvement. A case in point are the different reactions ensuing in Italian doctor–patient dialogues from the use of the third person singular (politeness form) vs. the first person plural (involvement form):

(14) [doctor to patient]

Allora,	come	st-a?	vs. Allora,	come	andiamo?
So	how	stay-3sing	So	how	go.1pl

'So, how are you then?' vs. 'So, how are we doing?'

One more example is the use of the third person in place of the first and second persons in baby talk and in emotive language in general (this use is probably iconic in the former case since baby talk in its first stages ignores the deictic use of first and second persons; see Schlegoff, 1996):

(15) [grandmother to granddaughter]

Lo	dà	un	bacio	alla
It	give.3sing	a	kiss	to the

nonna questa bella bambina?
grandmother this nice girl
'Will this nice little girl give her granny a kiss?'

Name-dropping is one more case in point. It consists in using a referential expression that is immediately identifiable only to a restricted number of persons. This results in evoking a relation of affinity or closeness between the speaker and the mentioned referent and, at the same time, in having the addressee either excluded from or included in such an exclusive circle of friends:

(16) [gossip writer in a television feature]
We went to George's [George Clooney's] to ask him about his latest film.

Greater attention to the social and ritual aspects implicit in the use of referring devices has been paid in the analysis of allocutives and of person referring expressions (in particular those referring to speaker and addressee). Brown and Gilman (1960) regard the different options available in many languages in their allocutive systems as a means for speech participants to manifest the relations existing between them in terms of power and solidarity. For example, a few Indo-European languages use an alternation between persons to refer to a speech participant. The use of the second person singular conveys a short distance in terms of solidarity and/or power, while other forms (e.g., the third person in German, Spanish, and some varieties of Italian; the second person plural in French and some varieties of Italian) signal greater distance along either or both of the axes. Japanese has been extensively studied in this connection since it has a rather complex system for the selection of referring expressions, with respect both to speaker and addressee and to third persons. This system expresses both the relative status of speaker and addressee and that of the speaker in relation to the object or person that is being talked about (see Ide and Yoshida, 1999). Nevertheless, the exact role played by each component (power, solidarity, degree of involvement) as well as their interaction remain, to a large extent, to be defined more accurately.

A promising line of research involves studies seeking to explain how referring mechanisms are selected on the basis of politeness strategies (Brown and Levinson, 1978) or face-saving moves. In his discussion of personal reference, Murphy (1988) points out the need to study in an integrated fashion how all the relevant parameters (i.e., speaker, addressee, referents, and bystanders) interact with each other. The *Rule of polite reference*, which Murphy (1988) proposes for personal reference, is expressed in terms of face-saving devices for both speaker and addressee.

When in a polite, cooperative conversation, the speaker chooses a referring expression:

1. that the speaker and addressee mutually believe that the addressee can use to pick out the referent uniquely;
2. that expresses a defensible speaker–referent relationship;
3. that is not more desirable than the addressee–referent relationship; and
4. that is consistent with the addressee's view of an appropriate speaker–referent relationship.

Nevertheless, Murphy himself observes that the politeness explanation is not sufficient to describe all possible reasons behind the selection of referring expressions. Some data seem to suggest, for example, that speakers try to avoid offending their addressees even if this may not cause any loss of social image. Orletti (1992) also agrees that this approach cannot explain all cases of selection of referring expressions and offers some examples that seem to demand that more components be brought to bear on this issue (Orletti, 1992: 327).

(17) [TV discussion on AIDS between Aiuti, Donat Cattin, and De Lorenzo; Ferrara is the chairman]

all'AIDS ed è stato sottosegretario
at the AIDS and has been undersecretary
alla Sanità ed è un deputato liberale
at the Health and is a deputy liberal

'Ferrara: Let's hear what an MP, Francesco De Lorenzo, thinks.'
'Donat Cattin: He's an MP but is also the president of the specialists in infectious diseases, who are the main players in this area of research.'
'Ferrara: Let me now introduce Mr De Lorenzo, MP. Could we put him on screen, please?'
'Aiuti: He retired 20 years ago.'
'Donat Cattin: He's the president of the Association of the specialists in infectious diseases.'
'Ferrara: Please, let's not get personal, Prof. Aiuti. Mr. De Lorenzo, you are the current president of the national committee on AIDS prevention and were undersecretary of the Health Department and are a Liberal MP'

In (17), the conflicting denominations used by the participants (Aiuti, Donat Cattin, and Ferrara) to identify De Lorenzo do not satisfy any referential needs. Nor do they reflect differences in how politeness is being handled. In part, they arise from the need to identify their referent's role in a way that is the most appropriate to the ongoing discourse. This need, however, fulfills a more general function, that of strengthening or weakening the referent's role as an argument in favor or against the discussants' diverging opinions. Furthermore, the conflict over the correct denomination of a third referent allows or forces the participants to define their own roles in the discussion. While Donat Cattin is in favor of De Lorenzo's line, Aiuti is against it. Finally, Ferrara has the strategic role of chairman, which includes, among other things, the power to decide which denomination should be used (see line 6).

In sum, socioethnographic approaches seem a promising field of research but must still be explored in depth. As they have often focused on how single referents are selected rather than on how referential chains are dealt with, it is not possible to compare them to the cognitive and conversation analysis studies cited so far. Further, the current lack of a common analytical model makes it difficult to summarize their results.

A Pragmatic Account

Despite differences in their goals and in the proposed models, the various approaches illustrated so far have some points of contact that bring the pragmatic dimension to the fore. Among them are (a) the recognition that the problem of anaphoric distribution in discourse may be profitably studied as a function of the speaker's communicative goals and (b) the recognition that it may be useful to include a recipient-oriented perspective into any descriptive model of the speaker's communicative goals. The latter implies that the speaker, by selecting a specific referring device, tries to achieve a desired effect in relation to the hearer's discourse model.

It may therefore be very useful to discuss the points made above as well as the various principles illustrated so far in the light of the Gricean pragmatic principles of conversational logic. A similar proposal is explicitly put forward by Huang (2000) and can be found in various passages in Schlegoff (1996), which invoke Gricean principles.

Fundamentally of Gricean origin is the idea that the "why that now" principle is "an omnirelevant issue for parties to talk-in-interaction" (Schlegoff, 1996: 439). That is, the idea that the addressee's interpreting activity arises from his or her attempt to understand the reasons behind the use of a given expression on the part of the speaker. On the basis of this principle, Schlegoff concludes that the speaker's primary aim as he uses a certain linguistic expression is to let the addressee understand his intentions behind the use of such an expression. In other words, the rationale guiding the selection of referring expressions is to be found in their ability to generate inferences regarding the speaker's intentions in the addressee's mind.

According to Huang (2000), the cognitively-oriented 'iconic' principles of anaphoric interpretation, which aim at effort minimization and result maximization (whereby the expected result is the addressee's ability to recognize the intended referent), can be regarded as instantiations of the principles of conversational logic in the realm of the encoding of referential relations. Huang proposes a series of principles of anaphoric interpretation (see Huang, 2000: 215), which derive from the Gricean maxims and the cooperation principle (as revised by Levinson, 1995).

Interactional exchanges in particular highlight the principles to which both speaker and addressee adhere in order to achieve their common goal. For instance, the repair mechanisms triggered by difficulties in the identification of a referent illustrate how the speaker progressively adapts to the hearer's knowledge state in conformity with the Informativeness Principle.

Huang's model, like cognitive models in general, focuses mainly on the goal of identifiability. Nevertheless, a Gricean pragmatic model (see the Gricean-based Relevance Theory, Sperber and Wilson, 1986) can also be invoked to explain phenomena contradicting such a goal, namely name-dropping. In that case, the Manner Rule seems to be flouted since the speaker does not use the most direct expression to guarantee identifiability. However, according to the general Relevance Principle of 'why that now' (or to the Cooperative Principle, in a Gricean perspective), the addressee tries to find out the reasons behind the

speaker's use of a certain expression, although we should keep in mind that its occurrence may not be motivated on grounds of the goal of identifiability but, rather, may be linked to the speaker's construal of her own social image and to how social roles define the relation between speaker and addressee.

In sum, a Gricean pragmatic approach can be a useful common background for the various lines of enquiry into the use of referential expressions presented here. It is of crucial importance, however, to view the 'logical behavior' of speakers in conversation not simply as aiming at the successful transfer of information (as is argued in cognitive-oriented approaches) but also as involving the construal and management of social relations between the speech participants (as well as other dimensions that have been explored even to a lesser degree).

Referential versus Attributive

A Barber, The Open University, Milton Keynes, UK

Donnellan's Contrast

Consider two utterances of the same sentence, S:

S: Smith's murderer is insane.

The first utterance, $U(S)_{ATT}$, is prompted by the speaker's discovery of Smith's savagely mutilated corpse roasting on a spit, with no culprit in evidence. The second, $U(S)_{REF}$, is prompted by an observation years later of a defendant, Jones, seen cross-eyed and frothing at the mouth as he climbs into the dock on trial for Smith's murder. As it happens, the real killer, Robinson, goes free and is perfectly sane (his crime notwithstanding) while Jones, though falsely charged, is as mad as he looks. Many find it natural to suppose that the speaker of $U(S)_{ATT}$ has said nothing correct about anyone while the speaker of $U(S)_{REF}$ has said something correct about Jones, even if perhaps she has used the wrong words to do so. This is an example of the contrast between what Keith Donnellan labels – misleadingly on some views – attributive and referential uses of definite descriptions. Here is Donnellan's own characterization of the contrast:

> A speaker who uses a definite description attributively in an assertion states something about whoever or whatever is the so-and-so. A speaker who uses a definite description referentially in an assertion ... uses the description to enable his audience to pick out whom or what he is talking about and states something about that person or thing .... [T]he definite description is merely one tool for doing a certain job – calling attention to a person or thing – and in general any other device for doing the same job, another description or a name, would do as well. In the attributive use, the attribute of being the so-and-so is all important, which it is not in the referential use (Donnellan, 1966a: 285).

Attempts to account for how the contrast arises lie at the heart of work on the nature of the semantics/pragmatics boundary. This entry looks at the origins of Donnellan's distinction in his criticism of Russell's theory of descriptions, and then considers two approaches to the contrast, one that treats it as pragmatic in origin and the other that treats it as a genuinely semantic distinction.

Donnellan's Use of the Contrast against Russell

Donnellan introduced the distinction with a view to undermining Russell's theory of definite descriptions (Russell, 1905, 1919). Russell argued that the surface form of (1) below is misleading. It has an underlying logical form that, when interpreted, delivers the truth condition set out in (2):

(1) 'The fish jumped'

(2) An utterance of the sentence in (1) is true if and only if $\exists x$ ((x is a fish & $\forall y$ (y is a fish $\rightarrow x = y$)) & x jumped)

Definite descriptions, in other words, are non-namelike: nothing in the underlying logical form of sentences containing them corresponds to an object referred to by 'The fish.' (Russell also held that ordinary names are non-namelike in this respect too, but that is another matter.) By denying that the semantic function of definite descriptions is to pick out a single object in order then to say something about it, Russell hoped to solve a variety of puzzles. For example, it became possible to explain how a definite description can be used meaningfully even when less than one (as in (3)–(4)) or more than one (as in (5)) contextually salient object satisfies the description; or how identity statements made using definite descriptions can be informative as in (6) when an equivalent name would not be (as in (7)).

(3) 'The king of France is bald': false but meaningful.

(4) 'The king of France does not exist': meaningful and true.

(5) 'The woman in the magician's box has been sawn in half': false but meaningful.

(6) 'The author of the Waverley novels is Walter Scott': true and informative.

(7) 'Walter Scott is Walter Scott': true but uninformative.

From Russell's perspective, these cases are puzzling only if one assumes that the entire semantic function of a phrase of the form 'the ...' is to single out an object that uniquely satisfies the property expressed by '...', in order then to say something about it with the rest of the sentence. If truth conditions are instead assigned along the pattern in (2), these examples cease to be troublesome.

According to Donnellan (1966a), Russell's theory copes adequately with $U(S)_{ATT}$ but not with $U(S)_{REF}$. It assigns the same truth conditions to both utterances:

> An utterance of S is true if, and only if, $\exists x$ ((x murdered Smith & $\forall y$ (y murdered Smith $\rightarrow x = y$)) & x is insane)

Intuitively, $U(S)_{REF}$ would need to be withdrawn if Jones were in fact sane, while $U(S)_{ATT}$ would not be affected; and Robinson's mental health is irrelevant to

$U(S)_{REF}$ despite being highly relevant to $U(S)_{ATT}$. Donnellan took these intuitions, and others elicited by similar cases (e.g. 'Who is the man drinking a martini?' asked of someone who is in fact drinking water) to refute Russell's theory, at least in so far as the latter was intended to give a comprehensive account of definite descriptions.

It is unclear whether Donnellan thought his distinction had a pragmatic or a semantic origin. The fact that he takes it to refute Russell suggests he took it to be semantic. Russell's theory was, after all, a theory of the semantics of definite descriptions, not of their pragmatics. But he persistently talks of *uses* of definite descriptions, and at one point even writes explicitly that

> [. . .the] grammatical structure of the sentence seems to me to be the same whether the description is used referentially or attributively: that is, it is not syntactically ambiguous. Nor does it seem at all attractive to suppose an ambiguity in the meaning of the words; it does not appear to be semantically ambiguous. (Perhaps we could say that the sentence is pragmatically ambiguous: the distinction between roles that the description plays is a function of the speaker's intentions.) (Donnellan, 1966a: 297)

It is possible that Donnellan's position, further developed in Donnellan (1968), is just that no pragmatic theory is available to complement Russell's semantic theory in such a way as to explain referential uses as well as attributive ones. In that case, even if there is no semantic ambiguity, Russell's semantic theory would have to be rejected. But a more likely explanation of the contrary indicators in his paper is the primitive understanding of the semantics/pragmatics boundary at the time.

Whatever we take Donnellan's own view to be, most reactions to his contrast can be classified according to whether they treat the difference as semantic or as pragmatic. Some treat his contrast as a difference in use alone, while others claim the difference in use is a symptom of a genuinely semantic ambiguity. Pragmatic approaches are now slightly more popular, but the only genuinely uncontroversial claim to be made in this area is that reflection on Donnellan's contrast has forced everyone to be clearer than they were about what the semantics/pragmatics distinction actually is (*see* **Semantics–Pragmatics Boundary**). In what follows I will outline two paradigmatic treatments, one from each camp.

Pragmatic Treatments (Kripke)

Kripke's role as a critic of Russell's theory of reference is well known (Kripke, 1980), so it might seem

Figure 1 Russell's theory of names as definite descriptions.

surprising that in this context he is Russell's defender. The explanation is simple: Russell's theory of descriptions has two components. On the one hand, and as detailed above, he claimed that definite descriptions have a complex logical form that is not easily read off from their surface structure. But he also claimed that ordinary names are in fact disguised definite descriptions (Figure 1). After all, the same puzzles that his theory of the logical form of descriptions is supposed to solve arise equally for ordinary names, so this is a natural extension. In *Naming and necessity*, Kripke rejects the claim that ordinary names are covert definite descriptions but leaves Russell's treatment of definite descriptions as such largely unchallenged. In Kripke (1977) he defends Russell, against Donnellan's criticism at least.

Kripke's response to Donnellan is methodologically elegant (1977: 3c). He imagines a population that has a language like English but, stipulatively, it has a Russellian semantics for definite descriptions. He then asks whether the contrast between referential and attributive uses of definite descriptions would arise in such a population. It would, he argues. Indeed, Kripke suggests, if speakers of this language did not use 'The F is G' at all, but instead used 'there is an F, identical with anything that is F, and it is G,' an analogue of Donnellan's distinction would still arise. They would use this sentence when they wished to attribute G-ness to something they, mistakenly, believed to be the unique possessor of F-ness. Kripke infers from this that existence of Donnellan's contrast *among speakers of English* does not undermine the claim that English definite descriptions have the semantics Russell says they do.

Kripke's position can be explicated using a famous example due to Paul Grice (1975: 33). A letter of reference for an academic position contains the following evaluation of a weak candidate:

> Mr X's command of English is excellent, and his attendance at tutorials has been regular. Yours, etc.

The referee is damning the candidate with faint praise. But in other contexts the sentence could be used without any negative insinuation. This possibility hardly shows that the sentence itself is semantically ambiguous, having a faint-praise sense and a neutral sense. Likewise, Donnellan's contrast does not, according to Kripke, show that S itself is semantically ambiguous. (Grice's own views on Russell's theory are in his 1989 title; see also Neale, 1990: 78; section 3.5.)

The challenge with all pragmatic theories is to provide more than a hand-waving demonstration of how the relevant phenomenon arises systematically from a feature of the conversational context rather than a feature of syntax. Kripke's derivation is based on a distinction he introduces between speaker's referent and semantic referent, which is itself a special case of Grice's distinction between what a speaker means 'on an occasion,' a matter of their intention, and what the expression means 'timelessly.' Roughly, the identity of the semantic referent for a particular use of a referring expression is governed by the conventional rules of the speaker's language or idiolect. These semantic rules establish a condition that something must meet in order to be the referent of the expression whenever it is used. The speaker's referent is what she wishes to talk about and which, so she will typically believe, meets the conditions for being the semantic referent of the expression she therefore uses in an effort to satisfy this wish. Much of the time semantic referent and speaker's referent will be the same entity. But if for example the speaker is mistaken in believing, of the object she wishes to talk about, that it meets the condition for being the semantic referent of the expression she uses, then the two can be distinct.

Using this distinction, Kripke explains how Donnellan's phenomenon would arise in a language stipulated to assign Russellian truth conditions to definite descriptions. The contrast would emerge out of a distinction between two kinds of wishes its speakers could have when using a definite description. One kind of wish would be to talk about the semantic referent as such, no matter which object that should turn out to be. Another kind of wish would be to say something about a specific object, where use of the definite description would fix the audience's attention on that object whether or not the object is in fact the semantic referent. Kripke claims that this difference in wish would not affect the identity of the semantic referent.

These considerations do not show that English is a Russellian language, with 'the F is G' suffering from no lexical or structural ambiguity. They are compatible with its being the case that some utterances of this sentence are true just in case there is a unique F and it is G, while others are true just in case *an entity the speaker has in mind is uniquely F* is G. But in the absence of independent evidence, Kripke thinks the default assumption should be the simpler one: definite descriptions have a unitary, Russellian semantics. In support of this claim that the no-ambiguity position should be the default, he notes that there is something slightly awkward about describing $U(S)_{REF}$ as true . . . about describing the utterance of $U(S)_{REF}$ as strictly true, even if it manages somehow to convey a true proposition.

Semantic Treatments (Wettstein)

Kripke in effect throws down a challenge: show that the difference in use has semantic significance. Wettstein (1981) takes up that challenge. However, his understanding of the attributive/referential distinction differs importantly from Donnellan's. In Donnellan's original examples of referential use, the object referred to fails to be a unique satisfier (in the context) of the descriptive element of the definite description. If all examples were like this, and the existence of a semantic distinction depended on the intuition that such examples were true, the semantic ambiguity thesis would be in trouble. According to Wettstein, Donnellan could and should have illustrated the referential use using only examples in which the object the speaker intends to refer to **is** a unique satisfier (in the context) of the descriptive element of the definite description. So suppose now that Jones *is* guilty, and no one else is. Wettstein takes the distinction between $U(S)_{REF}$ and $U(S)_{ATT}$ to consist in a difference in the proposition the sentence semantically expresses on each occasion. The proposition expressed by sentences containing a definite description can have either of two structures, he holds. In referential uses, the proposition is singular. That is, among its constituents, and corresponding to the definite description, is a single object – Jones, say. In attributive uses, the proposition has a general or quantificational structure so that Jones is not a constituent of the proposition. These two propositions are distinct even though the single object must be the unique satisfier of the description for the singular proposition to be true. So Wettstein sees no need to follow Donnellan (as he is often interpreted) in making the further claim that referential uses can be correct even if the referred to object is not the unique satisfier of the description. This further claim is far more tenuous (Kripke, 1977; Lockwood, 1975; Wiggins, 1975).

This clarification of the distinction undermines a widespread reason for denying there is any semantic ambiguity, but it does not show that there is one. Wettstein argues for the positive thesis by noting that referentially used descriptions express a determinately true or false proposition, despite being 'incomplete.' Thus it is possible to utter (8) truly despite there being more than one table in existence.

(8) 'The table is covered in books'

How is determinacy achieved in the face of incompleteness? According to Wettstein, standard Russellian answers fail. A typical answer would be to say that the incomplete description is tacitly completed in some way. For example, 'table' in (8) is elliptical for (9).

(9) 'table in the north-east corner of the kitchen at 36 Richmond Way in Harwich, England'

Wettstein responds that how the description is completed is itself indeterminate. It could equally have been (10).

(10) 'table beside the kitchen window at 36 Richmond Way in Harwich, England'

The same table satisfies each description uniquely, but the descriptions are nonetheless distinct. So no general proposition is uniquely determined. The determinacy of incomplete referential uses *can* be explaining by supposing that definite descriptions function, like demonstratives, to pick out some contextually and conversationally salient table, Wettstein adds. But explaining the determinacy this way has too high a cost for Russellians: the proposition semantically expressed would need to be singular.

Developments

Not everyone has found this argument convincing (see Soames, 1986, Salmon, 1982, Wettstein, 1983, and Reimer, 1998, for discussion). But there are other kinds of argument in favour of interpreting the contrast as semantic. In a different paper Donnellan himself argued for the ambiguity thesis by considering the behavior of descriptions inside modal operators:

> Consider the ambiguity of the counterfactual sentence: "If the President were the author of 'On Denoting,' we would not be in Vietnam." This may be construed as a sentence about Johnson, but there is a second reading on which it is not about him. If it is construed as being about him, then the relevant identity statements give rise to legitimate substitutions; otherwise not. On either reading, the sentence as a whole is non-truth functional, because counterfactual. The ambiguity is not to be explained by supposing that 'the President' refers to Johnson in both cases but that in one case the sentence ascribes a property to him but on the other reading it does not. Rather, on one reading 'the President' does not refer to Johnson at all (Donnellan, 1966b: 687)

Important to the resolution of the issue is the observation, ignored here for brevity, that the referential/attributive contrast may apply to other expressions, including indefinite descriptions, demonstratives, and perhaps even pronouns and names. (For further arguments favouring the semantic position, see Devitt, 1981: 2.5–2.7, 1998, 2004, and Devitt and Sterelny, 1999.)

Reflexivity

M Silverstein, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Reflexivity is a term variously applied to certain properties of the grammatical systems and lexical forms of language, to the meanings of such forms, to the mental or cognitive capacities of language users, to the textually formed discourses that users create, to states of agentive consciousness of people acting in social situations, and to the special case of researchers as agents seeking to understand social behaviors such as the use of language in society.

Reflexivity as a grammatical phenomenon indicates the referential identity or equivalence of two grammatical terms, generally propositional arguments, of a clause-sized grammatical phrase. The prototype is the relationship of grammatical subject to grammatical object, revealed in English *-self* reflexive pronouns, but indirect reflexives (Takelma), reflexive possessors of nominals (Slavic languages), cross-clause reflexives (Inuit), etc., also are found.

Reflexivity is a lexical phenomenon, in that certain words of a metalinguistic sort, terms denoting or describing phenomena in language itself, are examples in the real world of the very phenomenon. Conceptualizing metalinguistic reflexivity, some logicians devised a special terminological contrast, (German) *autologisch* (English: *autological*, also *homological*) vs. *heterologisch* (*heterological*) for a logical predicate, particularly an adjective, denoting a property true of the metalinguistic form itself; hence English *short* is a (relatively) short word form of one syllable, and autological, while *long*, of similar form, is heterological. A large number of the Indian grammatical terms for describing derivational phenomena of Sanskrit, now applied more widely as standard technical terms, are themselves examples of the phenomenon denoted, e.g., *tat* + *puruṣa-* (literally, 'that'+'man') denotes the class of compound stems composed of modifier (here, the stem of a third person anaphor) plus modified; thus *tatpuruṣa-* is itself a tatpuruṣa compound (meaning 'his person').

Reflexivity is, as well, a fact of denotational usage. Among the grammatical and lexical categories of languages, the token-reflexives, or shifters (*see* **Deixis and Anaphora: Pragmatic Approaches**), or indexical-denotational forms, are pervasive and universal. Most obviously, these include the paradigms of personal deictics such as French singulars *je/moi/me/mon* and *tu/toi/te/ton*, the referents of which can be located only when one can identify the individual who is communicating with the instance, or 'token,' of the form, and the individual to whom the instance or token has been directed. The reference of such forms reflexively depends on the actual role inhabitance in the communicative event in which a token is used. Not only nominal – functionally referential – but pervasive verbal – hence, predicational – categories show token reflexivity of this sort; rules of token-reflexivity underlie the language structure and its anchoring to specific contexts of communication as experienceable events.

Reflexivity, for some writers, also means having a conceptual capacity to communicate token-reflexively, that is, having a metacommunicative intentionality, whether conscious or, to varying degrees, unconscious. Deploying token-reflexivity in respect of community or group norms for communicating, so that language use is appropriate to particular contextual conditions and effective in bringing about contextual conditions, presumes such a reflexive, or 'metapragmatic,' level of cognition (*see* **Metapragmatics**). This is most transparently revealed in explicit primary performative utterances, where reflexively used forms (such as the Kiksht (Wasco-Wishram) metapragmatic verb/root -pg̣na- in yamupg̣na 'diálax̣' 'I-name/pronounce-you 'Diáiax.'') token- reflexively describes as true of the event in which it is used, the effective (i.e., causally consequential and successful) act of which the very utterance of the formula with its token consists. Such possibly performative effects of

Reflexivity

M Silverstein, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Reflexivity is a term variously applied to certain properties of the grammatical systems and lexical forms of language, to the meanings of such forms, to the mental or cognitive capacities of language users, to the textually formed discourses that users create, to states of agentive consciousness of people acting in social situations, and to the special case of researchers as agents seeking to understand social behaviors such as the use of language in society.

Reflexivity as a grammatical phenomenon indicates the referential identity or equivalence of two grammatical terms, generally propositional arguments, of a clause-sized grammatical phrase. The prototype is the relationship of grammatical subject to grammatical object, revealed in English *-self* reflexive pronouns, but indirect reflexives (Takelma), reflexive possessors of nominals (Slavic languages), cross-clause reflexives (Inuit), etc., also are found.

Reflexivity is a lexical phenomenon, in that certain words of a metalinguistic sort, terms denoting or describing phenomena in language itself, are examples in the real world of the very phenomenon. Conceptualizing metalinguistic reflexivity, some logicians devised a special terminological contrast, (German) *autologisch* (English: *autological*, also *homological*) vs. *heterologisch* (*heterological*) for a logical predicate, particularly an adjective, denoting a property true of the metalinguistic form itself; hence English *short* is a (relatively) short word form of one syllable, and autological, while *long*, of similar form, is heterological. A large number of the Indian grammatical terms for describing derivational phenomena of Sanskrit, now applied more widely as standard technical terms, are themselves examples of the phenomenon denoted, e.g., *tat* + *puruṣa-* (literally, 'that'+'man') denotes the class of compound stems composed of modifier (here, the stem of a third person anaphor) plus modified; thus *tatpuruṣa-* is itself a tatpuruṣa compound (meaning 'his person').

Reflexivity is, as well, a fact of denotational usage. Among the grammatical and lexical categories of languages, the token-reflexives, or shifters (*see* **Deixis and Anaphora: Pragmatic Approaches**), or indexical-denotational forms, are pervasive and universal. Most obviously, these include the paradigms of personal deictics such as French singulars *je/moi/me/mon* and *tu/toi/te/ton*, the referents of which can be located only when one can identify the individual who is communicating with the instance, or 'token,' of the form, and the individual to whom the instance or token has been directed. The reference of such forms reflexively depends on the actual role inhabitance in the communicative event in which a token is used. Not only nominal – functionally referential – but pervasive verbal – hence, predicational – categories show token reflexivity of this sort; rules of token-reflexivity underlie the language structure and its anchoring to specific contexts of communication as experienceable events.

Reflexivity, for some writers, also means having a conceptual capacity to communicate token-reflexively, that is, having a metacommunicative intentionality, whether conscious or, to varying degrees, unconscious. Deploying token-reflexivity in respect of community or group norms for communicating, so that language use is appropriate to particular contextual conditions and effective in bringing about contextual conditions, presumes such a reflexive, or 'metapragmatic,' level of cognition (*see* **Metapragmatics**). This is most transparently revealed in explicit primary performative utterances, where reflexively used forms (such as the Kiksht (Wasco-Wishram) metapragmatic verb/root -pg̣na- in yamupg̣na 'diálax̣' 'I-name/pronounce-you 'Diáiax.'') token- reflexively describes as true of the event in which it is used, the effective (i.e., causally consequential and successful) act of which the very utterance of the formula with its token consists. Such possibly performative effects of

any utterance whatsoever – as much constructing as construing the world-as-denoted – are a constant concern of reflexive constructivism as an epistemological stance.

In the study of cultural texts , e.g., in literary and media criticism, reflexivity is the quality of signaling a metapragmatic relationship of a text to its genre conventions and intertextual field of comparison. An art work thematically depicting 'doing art'; advertisements that quote or spoof other advertisements or that imply with a wink that addressees know this is one; a film that sets up a scene that is diagrammatically like a famous earlier one, etc. – these all show textual reflexivity, and, by interpretative inference, reveal that the communicators – senders and receivers – too, probably have the metapragmatic agentive consciousness to formulate and understand the reflexive message.

Reflexivity is, increasingly, becoming an important concept in research methodology in the social and behavioral sciences, as well as in contemporary humanistic fields. Originally seen as merely a source of potential bias or error against which positivist social and behavioral science had to struggle, we now recognize the researcher's own reflexive metapragmatic consciousness and inevitable actual participant status in any contexts of research on humans. This makes all research a dialectical process of moving, reflexively, back and forth between 'objective' and inductive accounts of data in a research context, on the one hand, and on the other, a metapragmatic analysis of the communicative situation in which such data arise to and for the researcher.

Reflexivity in Sociolinguistics

B Johnstone, Carnegie Mellon University, Pittsburgh, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

In pragmatic theory, 'reflexivity' labels the ways language inevitably refers to itself (Jakobson, 1960; Silverstein, 1979; Lucy, 1993; Taylor, 2000). The reflexive function of language is easiest to see in overtly metalinguistic genres such as dictionaries and usage guides, but every utterance is potentially normative, providing a model for one way utterances can sound and be structured and how recurring forms can be linked with recurring functions.

Variationists' own discourse is reflexive. People who interact and identify with one another may tend to talk alike, but 'dialects' and 'varieties' are artifacts of the ways sociolinguists talk about talk. If we ignore the reflexivity of our work, we risk mischaracterizing its value, which is greater in illuminating processes of social identification and linguistic change than in describing 'varieties' or 'dialect areas.' Our choices about what to study and the claims we make about it are always liable to prescriptive, normative interpretation, as claims about what 'authentic' dialect speakers do. If we ignore this when we talk about our work to the people we study, we risk mystifying or offending them.

The talk of the people we study is also reflexive. Laypeople have their own ways of describing varieties of speech (Preston, 1989). Folk-linguistic categories and boundaries are reflected, modeled, and created in activities involving explicit talk about talk, such as folk dictionaries or interactive dialect websites (Johnstone and Baumgardt, 2004). This also happens in metalinguistic activities that foreground the social meanings of linguistic features less explicitly, such as momentarily assuming an exaggerated accent (Schilling-Estes, 1998). Such activities may feed into the sociolinguistic processes that lead to change.

any utterance whatsoever – as much constructing as construing the world-as-denoted – are a constant concern of reflexive constructivism as an epistemological stance.

Reformation, Northern European

N McLelland, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The Reformation began in 1517 as a protest by the German monk Martin Luther against abuses within the Catholic church. It ultimately resulted in the emergence of the various Protestant traditions alongside the Catholic church in Europe, but it also had profound cultural consequences, changing the way both the vernaculars and the 'sacred' biblical languages (Latin, Greek, and Hebrew) were perceived, taught, and studied.

Translations of the Bible into the Vernacular Languages

A central tenet of the Reformation was the primacy of biblical authority, and the belief that ordinary people should be able to read the Bible in their own language. In Scandinavia, the New Testament was translated into Danish in 1524, into Swedish in 1527, and into Finnish in 1551. The full Bible was translated into Swedish in 1541, and into Icelandic in 1584. In England (where Wycliffe had produced a handwritten translation as early as the 1380s), William Tyndale's translations were printed from 1525 to 1531. Martin Luther's German Bible translation (the New Testament, 1522, the full Bible, 1534) was far from the first printed (the first appeared in 1466) but enjoyed massive influence. Written in an idiomatic, lively, and highly readable High German, it was cited as the model of good language use throughout Protestant Germany for centuries to come. Johannes Clajus's *Grammatica Germanicae Linguae* (1578) – the most influential German grammar well into the 17th century – claims in the first edition to be based on the German language *ex Bibliis Lvtheri Germanicis et aliis eivs libris collecta* 'taken from Luther's German Bible and others of his books.' So great was the authority of the Lutheran High German Bible that it was widely used in churches and schools throughout Northern Germany, even though these areas in fact spoke the radically different Low German dialects and had to learn High German as a foreign language. Ultimately, High German would replace Low German altogether in the north as the language of schooling, church, and administration.

In the Low Countries, the Protestant provinces of the north, which had successfully rebelled against the rule of the Catholic Spanish, ordered the first translation of the Bible into Dutch directly from Greek and Hebrew sources in 1618/19. The so-called *Statenvertaling* (literally 'States' translation'), printed in 1637, was the work of a committee of representatives of all the provinces, who sought a supraregional form of the language, avoiding any linguistic forms which were restricted to certain dialect areas. The language of the *Statenvertaling*, used in churches and schools, had considerable influence on the further development of Dutch linguistic norms. In Scandinavia, the Reformation likewise provided the key incentive to turn Swedish and Danish (also used in Norway) into written languages, and languages of

Acknowledging the reflexivity of variationist discourse and the discourse variationists study requires methodological reflexivity in a more general sense: systematic self-reflection about how researchers' ways of talking about things constrain what they are likely to see.

Introduction

The Reformation began in 1517 as a protest by the German monk Martin Luther against abuses within the Catholic church. It ultimately resulted in the emergence of the various Protestant traditions alongside the Catholic church in Europe, but it also had profound cultural consequences, changing the way both the vernaculars and the 'sacred' biblical languages (Latin, Greek, and Hebrew) were perceived, taught, and studied.

Translations of the Bible into the Vernacular Languages

A central tenet of the Reformation was the primacy of biblical authority, and the belief that ordinary people should be able to read the Bible in their own language. In Scandinavia, the New Testament was translated into Danish in 1524, into Swedish in 1527, and into Finnish in 1551. The full Bible was translated into Swedish in 1541, and into Icelandic in 1584. In England (where Wycliffe had produced a handwritten translation as early as the 1380s), William Tyndale's translations were printed from 1525 to 1531. Martin Luther's German Bible translation (the New Testament, 1522, the full Bible, 1534) was far from the first printed (the first appeared in 1466) but enjoyed massive influence. Written in an idiomatic, lively, and highly readable High German, it was cited as the model of good language use throughout Protestant Germany for centuries to come. Johannes Clajus's *Grammatica Germanicae Linguae* (1578) – the most influential German grammar well into the 17th century – claims in the first edition to be based on the German language *ex Bibliis Lvtheri Germanicis et aliis eivs libris collecta* 'taken from Luther's German Bible and others of his books.' So great was the authority of the Lutheran High German Bible that it was widely used in churches and schools throughout Northern Germany, even though these areas in fact spoke the radically different Low German dialects and had to learn High German as a foreign language. Ultimately, High German would replace Low German altogether in the north as the language of schooling, church, and administration.

In the Low Countries, the Protestant provinces of the north, which had successfully rebelled against the rule of the Catholic Spanish, ordered the first translation of the Bible into Dutch directly from Greek and Hebrew sources in 1618/19. The so-called *Statenvertaling* (literally 'States' translation'), printed in 1637, was the work of a committee of representatives of all the provinces, who sought a supraregional form of the language, avoiding any linguistic forms which were restricted to certain dialect areas. The language of the *Statenvertaling*, used in churches and schools, had considerable influence on the further development of Dutch linguistic norms. In Scandinavia, the Reformation likewise provided the key incentive to turn Swedish and Danish (also used in Norway) into written languages, and languages of

education and administration (where Latin and Low German had previously been used).

Codifying the Vernacular: Early Orthographies, Grammars and Dictionaries of the Vernacular Languages

The spread of literacy among ordinary people, so important to the Reformation, was made possible by the spread of printing with movable type in Europe (traditionally said to have begun in Germany in the 1450s). Together, printing and the growth of a reading public led to an increased interest in standardizing the vernacular – first its spelling, later its grammatical forms too. The earliest text to call itself a German grammar, Valentin Ickelsamer's *Teutsche Grammatica* (c. 1534), is less a grammar in our sense than a primer to teach reading and writing, concentrating largely on spelling and pronunciation. It builds on a tradition of earlier primers and guides for printers (the anonymous *Schrylfftspiegel,* 1527, Kolroß' *Handbüchlin tütscher Orthographi* in 1530, Fabian Frangk's *Orthographia Deutsch,* 1531, Meichßner's *Handbüchlin gruntlichs berichts, recht vnd wolschryben,* 1538), all of which sought greater uniformity in spelling according to the principle 'write as you speak.' In the Low Countries, Lambrecht's *Néderlandse spellinghe* (1550) was followed by a number of other orthographies, all published in the south (today's Belgium). It was based on Lambrecht's own Ghent dialect, but allowed for other spellings reflecting the pronunciations of other dialects – for instance, not just *geen*, but also *gein* or *gien* for 'no, none.' The first attempt at a supraregional Dutch spelling norm, Pontus de Heuiter's *Nederduitse orthographie* (1581), advocated a phonetic and maximally economic spelling, for instance, preferring the spelling *ic* or *ik* to the usual *ick*. The leaders of the Danish Reformation adopted a Danish orthography already elaborated by the printer Christiern Pedersen (1480–1554), which was largely accepted from the 1530s onwards. (Efforts to codify the spelling of the other Scandinavian languages are not found until the 17th century.) In England, where spelling practice reflected a jumble of habits brought in by Norman copyists, etymological spellings, and false etymological spellings, there were various attempts at more or less radical reforms. John Hart, influenced by the attempts of Louis Meigret to introduce phonetic spelling in French, hoped to restore the one-to-one relation between sounds and letters in *An Orthographie* (1569) and *A methode or comfortable beginning for all the unlearned* (1570); Thomas Smith's proposals in his *De recta et emendata linguae anglicanae scriptione* (1568) were more moderate.

The high value attached by Protestantism to the biblical word in translation, supported too by the humanist impetus that had begun in Italy with the so-called *questione della lingua* and spread north to France, Spain, and Portugal, raised the perceived value of the vernacular languages. Indeed, Luther's insistence on translating the Bible according to sense rather than literally, and on following German idiom, reflected this new-found confidence in the value of the vernacular in its own right. The vernaculars now came to be seen as amenable to systematic study no less than Latin, and in the latter part of the 16th century humanist grammars of German, English, and Dutch began to appear just as they had for the Romance vernaculars some decades earlier. In Germany in particular, attempts to establish a shared written language also reflect the beginnings of a cultural patriotism, a reaction to the political disunity caused by the Reformation. Grammars and textbooks were also produced for practical purposes, finding a ready market of learners who needed languages for travel or trade. Jacques Bellot (England) is just one example of several French Protestant refugees who earned their living by teaching in England, the Netherlands, Switzerland or Germany, and who published texts for learning French in the 16th century; in Germany, Brücker's (1620) primer of German may, in turn, have been written to help the French- and Dutch-speaking Reformed refugee communities who had been allowed to settle in Frankenthal in the 16th century.

The first grammars tried to show that the vernaculars in question were **equal** to Latin by showing that they were **similar** to it, forcing the vernacular into the straitjacket of Latin grammar. The most influential of the early German grammars, Clajus (1578), maintains six cases as in Latin (German, in fact, only marks four). In England, Bullokar's *Bref grammar for English* (1586), printed using his own reformed spelling, maintains that English shares four genders and five cases with Latin, though Bullokar concedes that in English four of the five cases are identical in form. The Dutch *Twe-spraack vande Nederlandse letterkunst* (1584) – published under the aegis of the Amsterdam *Rederijkerskammer* (approximately 'language society') – likewise maintains six cases. It is more innovative, though, in its treatment of verb conjugation, identifying five groups according to the pattern of changes in the stem vowel in present, preterite, and participle, a schema that reflects observation of the Dutch language rather than any Latin model. Innovative too was its attempt to find vernacular equivalents for Latin grammatical terminology. At around the same time, the Belgian mathematician Simon Stevin (1548–1620) also coined native equivalents for the terminology of mathematics and physics

in his *De Beghinselen der Weeghconst* [...] ('The principles of weighing [...],' 1586) to show that the vernacular was no less capable of expressing scientific concepts than Latin. Many of his coinings become established in Dutch, and his efforts also influenced the most important 17th-century German language theorist, Schottelius. In England, numerous treatises on terminology reflect a similar preoccupation with making scientific knowledge more accessible – the best-known, though not the first, promoter of this idea was Francis Bacon (1561–1626).

Pedagogical Reform and the Study of Latin

The first German grammars (Albertus, 1573, Ölinger, 1574, Clajus, 1578), aimed in part at foreigners wishing to learn German, are in Latin. But both Bullokar's *Bref grammar* and the Dutch *Twe-spraack* are written in the vernacular itself, for they aimed to fulfill a different part of the humanist program – reforming the teaching of Latin in schools. Understanding the grammar of the native language was simply a step towards learning Latin; indeed the *Twe-spraack* does not move far beyond basic spelling and writing, since after this, pupils moved on to Latin. The 16th century also saw numerous new grammars of Latin written by humanists keen to improve the pedagogy of Latin. Increasingly these exploit the potential of the new technology of printing, using visual effects such as tables rather than running text to present paradigms, and different fonts for Latin and German – they assume that young learners will see the book themselves, rather than learning by rote from their master. The Latin grammar (1526) of the Reformation humanist Philipp Melanchthon not only became the standard text for use in schools in Protestant Germany, but was also widely used in Scandinavia and Russia, and served as a model for many grammars of the vernaculars.

Learning to Compare: Studies of the 'Sacred' Languages

Luther based his Bible translation not just on the Latin Vulgate translation of Jerome, but also on the original texts in Greek and Hebrew. In him, and in his close associate and advisor Melanchthon, the Reformation met the humanist ideal of careful textual interpretation on the basis of original sources, which meant, in turn, careful study of those original languages themselves: Latin, but also increasingly Greek and to some extent Hebrew. The spread of systematic study of Hebrew among Christian scholars began with the *De rudimentis hebraicis* (1506) of Reuchlin (1455–1522); in Calvinist Switzerland Hebrew instruction was gradually introduced in some theological colleges; within the Catholic tradition, Jesuit institutions across Europe also began to include Hebrew in the curriculum. Important concepts from the ancient grammatical traditions of Semitic (Hebrew and Arabic) now came to be applied in European linguistic study – in particular, the classification of sounds according to their place of articulation, and the notion of the **root** of a word. The idea of the root was to be adopted fruitfully by Schottelius (1663) in his groundbreaking analysis of German word formation.

The encounter between theology and humanist language study is most obvious in the *Harmonia Linguarum* ('Language harmony,' 1602) of the Hebraicist Elias Hutter, who presents parallel texts of the Bible in Latin, Greek, and Hebrew, alongside German. Cruciger's (1616) language harmony aimed to show that German is ultimately derived from Hebrew, but via Greek and Latin, by making explicit comparisons between the four languages. Indirectly, then, the comparisons of these languages in the service of biblical scholarship led to a more comparative approach to language study and to questions about genetic relationships among languages. (In a parallel development, the medieval Latin vernacular vocabularies were often expanded from the 15th century on into plurilingual dictionaries, which invited comparison of several **living** languages at once.)

The Vernaculars and the Question of the Original Language

Growing confidence in the worth of the vernacular sometimes took a faintly mystical turn. Luther claimed that some words could be expressed more perfectly in German than in any other language, in a passage from his *Sendbrief vom Dolmetschen*, 'On Translating. An Open Letter' (1960 [1530]: 192): "I do not know whether this word liebe ['dear, beloved'] can be said in Latin or other languages with such fullness of sentiment, so that it pierces and rings through the heart, through all the senses, as it does in our language." In his *Teutsche Grammatica* (c. 1534), Ickelsamer even suggested that German words contained hidden meanings like those that Jewish scholars found in their Cabbalistic studies of Hebrew.

Such beliefs that the words of one's own vernacular express meanings more perfectly than any other were often linked in the 16th and 17th centuries to patriotic arguments about which vernacular was closest to the original, Adamic language – for surely the words that Adam used to name the world around him originally expressed their meaning perfectly, as, for

instance, the Swiss Old Testament professor Bibliander (c. 1504–1564) had reasoned in his *De ratione communi omnium linguarum et literarum commentarius* ('Commentary on the common rational basis of all languages and letters,' 1548). The Flemish scholar Joannes Goropius Becanus (1519–1572/3) was one of the first to apply such arguments to 'prove' that his vernacular – Dutch – was the oldest language. He segmented proper names gleaned from history so as to resemble words in Dutch, to show that Dutch is the simplest language, whose monosyllabic words are found in the more complex lexemes of other languages, which must, therefore, be derived from Dutch. Though Becanus's fanciful etymologies were much derided, he stands at the head of a pan-Germanic tradition of efforts by scholars such as the Fleming Adrianus Schrieckius (1560–1621), Dutchman Abraham van der Myle (1563–1637), the Swedes Georg Stiernhielm (1598–1672) and Olof Rudbeck (1630–1702), or the German Justus-Georg Schottelius (1612–1676) to show that the ancestor of the Germanic languages was closer to the original language of mankind (whether that is taken to be Hebrew, or assumed to have been lost at the tower of Babel) than any other European vernacular (and therefore by implication superior to them). Such efforts reflect an increasing awareness of language change and an interest in language history, though it is not until the 18th century that the question of the origin of language(s) could be addressed without attempting to accommodate the biblical account of the Adamic language and the confusion of tongues at Babel.

Conclusion

The Reformation applied the humanist ideal of close philological study to the original Biblical texts, and exploited the technology of printing to disseminate translations of these texts into the vernacular for a broad readership. As the perceived value of the vernaculars increased dramatically, the slow process of their codification and standardization began. Meanwhile detailed study and comparison of the 'sacred' languages with one another and with the vernaculars provided a basis for studies of the genetic relationships between languages and of language change. But it is Gesner's *Mithridates* (1555), already giving samples of 22 languages and listing a great many more, that prefigures the expansion of the linguistic horizon well beyond the languages of Europe and the Bible in the centuries to come.

Introduction

Cross-Linguistic Variation: Principles and Parameters

Generative syntax attempts to capture both linguistic invariance and cross-linguistic variation by means of the theory of Principles and Parameters (*see* **Principles and Parameters Framework of Generative Grammar**). Principles express universal constraints, whereas parameters define and delimit the space of variation. Principles are rigidly fixed. For instance, X-bar theory (*see* **X-Bar Theory**) is a set of principles to constrain the internal structure of constituents that can be formed in the syntax. Each parameter offers a choice between two settings, which correspond to a particular set of syntactic properties. Depending on the parameter setting, a language will or will not display certain syntactic properties defined by the parameter. Some parameters are briefly illustrated in the next section.

The core grammar of a language is a system that is determined by the interaction of universal principles with the parameter settings for that language. The output of the core grammar is grammatical sentences of the language.

Registers and Language-Internal Variation

In specific registers of language use, we may come across an output that deviates from that of the core grammar, containing sentences that, in terms of the core grammar, are ungrammatical (Zwicky and Zwicky, 1982; Biber, 1995). The status of such register-related 'deviant' data is not entirely clear. We might wish to maintain that any deviant data are strictly ungrammatical and should be dealt with as usage (see Newmeyer, 2003: 700–702, for the difference between grammar and usage). However, the register-related deviant patterns are not chaotic; they can be seen as the product of different 'peripheral' grammatical subsystems of the language, specific to the particular register (see Chomsky, 1981: 8–15).

In this article, first, we show that the syntactic properties associated with particular registers should probably not be interpreted as resulting from parameter resettings. Rather, in some cases at least, register-specific data that deviate from the output of the core grammar can be seen as the result of the relaxation of one or more constraints of the core grammar. Next, we discuss register-related variation in English. (For discussions of register variation, see Zwicky and Zwicky, 1982; Janda, 1985; Biber, 1995; Barton, 1998; Horsey, 1998.)

Parameters: Some Examples

The Pro Drop Parameter

The pro drop parameter determines whether the pronominal subject of a finite sentence may routinely be deleted in a given language. In terms of the X-bar format in **Figure 1**, the sentence is conceived of as a projection of the inflection of the verb (I) (*see* **X-Bar Theory**).

The pro drop parameter is the basis of the difference between languages such as Italian (1a), in which a subject pronoun can be deleted, and those such as

Introduction

Cross-Linguistic Variation: Principles and Parameters

Generative syntax attempts to capture both linguistic invariance and cross-linguistic variation by means of the theory of Principles and Parameters (*see* **Principles and Parameters Framework of Generative Grammar**). Principles express universal constraints, whereas parameters define and delimit the space of variation. Principles are rigidly fixed. For instance, X-bar theory (*see* **X-Bar Theory**) is a set of principles to constrain the internal structure of constituents that can be formed in the syntax. Each parameter offers a choice between two settings, which correspond to a particular set of syntactic properties. Depending on the parameter setting, a language will or will not display certain syntactic properties defined by the parameter. Some parameters are briefly illustrated in the next section.

The core grammar of a language is a system that is determined by the interaction of universal principles with the parameter settings for that language. The output of the core grammar is grammatical sentences of the language.

Registers and Language-Internal Variation

In specific registers of language use, we may come across an output that deviates from that of the core grammar, containing sentences that, in terms of the core grammar, are ungrammatical (Zwicky and Zwicky, 1982; Biber, 1995). The status of such register-related 'deviant' data is not entirely clear. We might wish to maintain that any deviant data are strictly ungrammatical and should be dealt with as usage (see Newmeyer, 2003: 700–702, for the difference between grammar and usage). However, the register-related deviant patterns are not chaotic; they can be seen as the product of different 'peripheral' grammatical subsystems of the language, specific to the particular register (see Chomsky, 1981: 8–15).

In this article, first, we show that the syntactic properties associated with particular registers should probably not be interpreted as resulting from parameter resettings. Rather, in some cases at least, register-specific data that deviate from the output of the core grammar can be seen as the result of the relaxation of one or more constraints of the core grammar. Next, we discuss register-related variation in English. (For discussions of register variation, see Zwicky and Zwicky, 1982; Janda, 1985; Biber, 1995; Barton, 1998; Horsey, 1998.)

Parameters: Some Examples

The Pro Drop Parameter

The pro drop parameter determines whether the pronominal subject of a finite sentence may routinely be deleted in a given language. In terms of the X-bar format in Figure 1, the sentence is conceived of as a projection of the inflection of the verb (I) (*see* **X-Bar Theory**).

The pro drop parameter is the basis of the difference between languages such as Italian (1a), in which a subject pronoun can be deleted, and those such as

Figure 1 X-bar format.

English (1b), in which it cannot be deleted (Jaeggli and Safir, 1986; Rizzi, 1986).

(1a) Parla inglese
(1b) *Speaks English

The Italian sentence (1a) is understood as if it contained a subject. This can be shown by means of examples such as (1c) in which a reflexive pronoun *se stesso* ('himself') takes as its antecedent the understood subject of *parla* (*see* **Binding Theory**).

(1c) Parla sempre di se stesso.
Speak.PRES.3.SING always of himself
'He always speaks about himself.'

Various analyses of this have been put forward. It is sometimes proposed that the subject in such cases is a nonovert underspecified pronoun (*pro*) whose content is recovered through the agreement of the verb (cf. Rizzi, 1986). Alternatively, it has been proposed that the agreement inflection of the finite verb itself functions as a subject (see Alexiadou and Anagnostopolou, 1998). A third possibility is to assume that a pronominal subject can be deleted if the agreement inflection on the finite verb duplicates all its grammatical features. As can be seen, these accounts of the positive setting of the pro drop parameter tend to relate the phenomenon to some property of the verbal agreement. The agreement paradigm of the Italian finite verb is rich. The finite inflection has a distinct form for each person/number combination (*parlo*, *parli*, *parla*, *parliamo*, *parlate*, *parlano*, 'speak,' present tense). In the deletion account, for instance, rich agreement inflection allows the deletion of the subject pronoun because the feature content of the deleted subject can be recovered through the inflection. Thus, the pro drop parameter is set positively. For English, the parameter is set negatively; the finite inflection is 'poor,' with minimal variation for person and number (*speak*, *speaks*). Thus, the finite inflection does not duplicate the features of the subject and the content of a deleted subject is not recoverable through the verbal inflection. (For discussions of the correlation between inflection and the pro drop phenomenon, see Jaeggli and Safir, 1986; Alexiadou and Anagnostopolou, 1998).

It is assumed that a parameter underlies a cluster of properties. For instance, the different settings of the pro drop parameter are at the basis of the contrasts between English and Italian illustrated in examples (2)–(4). As shown by (2), Italian weather verbs such as 'rain' do not have an overt expletive subject, whereas English weather verbs must have an expletive subject, *it*. The examples in (3) show that a definite lexical subject may follow the verb in Italian, an option unavailable in English. Questioning the subject of a subordinate clause in Italian (4a) is compatible with the presence of the subordinating conjunction *che* 'that,' whereas the English analog in (4b) is unacceptable. Example (4b) is rendered grammatical by omitting the subordinating conjunction *that*.

(2a) Piove.
Rain.PRES.3.SING
'It is raining.'
(2b) *Esso piove.
It rain.PRES.3.SING
(2c) It is raining.
(2d) *Is raining.

(3a) Arriva Gianni.
(3b) *Arrives John.

(4a) Chi credi che abbia telefonato?
Who think.PRES.2.SING that have.SUBJ.3.SING telephoned
'Who do you think has phoned?'
(4b) *Who do you believe that has phoned?

Subject Omission in Finite Clauses in English

Although English does not routinely allow the subjects of finite clauses to be deleted, one type of finite clause may lack an overt subject (Wilder, 1994). This is illustrated in (5a).

(5a) [I am very upset] and [Ø will not talk to him any more].

In (5a) the subject of the first clause is realized by the pronoun *I*. In the conjoined sentence, the subject is implicit (represented by Ø). The understood subject of the second conjunct is syntactically active. It can, for instance, serve as an antecedent for reflexive elements:

(5b) [I am very upset] and [Ø will pour myself a drink].

The content of the deleted subject in the second conjunct is not recovered through rich verbal inflection – *will* carries no marking of person and number inflection. In English coordinated structures, the subject of

the immediately preceding coordinated clause, here *I*, allows the content of the deleted subject of the second conjunct to be contextually recovered.

Even though it is clear that an understood subject is associated with the second of the coordinated clauses, and even though interpretively this understood subject would seem to correspond to an overt pronoun, the understood subject in English coordinated structures cannot be equated with the deleted subject pronoun of the pro drop languages. In coordinate structures, subject ellipsis is only possible if the subject occupies the left edge of the clause (Wilder, 1994). Compare the paired examples in (6)–(9), in which the (b) examples violate the left-edge constraint on ellipsis:

(6a) I think that John is very nervous and [(he) will immediately pour himself a drink].
(6b) I think that John is very nervous and <u>that</u> [*(he) will immediately pour himself a drink].

(7a) He was angry but [(he) would probably try not to show it].
(7b) He was angry, but [<u>would</u> *(he) show it?].

(8a) John likes Mary but [(he) cannot stand her sister].
(8b) John likes Mary but [<u>Mary's</u> <u>sister,</u> *(he) cannot stand].

(9a) The book will be entertaining but [(it) may not be very innovative].
(9b) The book will be entertaining but [<u>very innovative</u> *(it) won't be].

The left-edge constraint does not restrict subject deletion in the pro drop languages:

(10a) Penso [<u>che</u> Maria tornerà presto].
Think.PRES.1.SING that Maria come back.FUT.3.SING soon
e [che Ø mi dirà tutto]
and that Ø me tell.FUT.3.SING everything
'I think that Maria will come back soon and will tell me everything.'
(10b) **Tornerà** Ø presto?
Come back.FUT.3.SING Ø soon
'Will he/she come back soon?'
(10c) [**questo libro**, Ø non lo voglio].
This book, Ø non it want.PRES.1.SING
'This book, I don't want.'
(10d) [**intelligente**, Ø non lo è].
Intelligent, Ø non it is.PRES.3.SING
'Intelligent, he is not.'

Furthermore, in Italian coordinated clauses the understood subject of the second conjunct need not be coreferential with that of the first conjunct. In (10e) the subject of the first conjunct is understood as the atmospheric subject (English weather *it*); in the second conjunct the subject is understood as *io* 'I.'

(10e) Ø faceva freddissimo e Ø
Ø make.PAST.3.SING very.cold and Ø
avevo perduto i miei guanti.
have.PAST.1.SING lost the my gloves.
'It was very cold and I had lost my gloves.'

Left-edge ellipsis in coordination, a property of the core grammar of English, is thus different from the subject deletion displayed in pro drop languages.

Argument Omission and Topic Drop

Several languages routinely allow the deletion of arguments (both subjects and objects) when these refer to contextually salient entities (discourse topics). The phenomenon is sometimes referred to as 'topic drop.' The examples in (11) illustrate object omission in Portuguese (Raposo, 1986: 381).

(11a) o Manel guardou Ø no cofre
Manuel kept Ø
da sala de jantar.
in.the safe of.the room of dining
'Manuel kept it in the dining room safe.'
(11b) eu disse ao António que pedise
I said to Antonio that ask.SUBJ.3.SING
ao Manel que guardasse
to Manuel that keep.-SUB.-3.SING
Ø no cofre da sala de jantar.
Ø in.the safe of the room of dining
'I told Antonio that he should ask Manuel to keep it in the dining-room safe.'

Other languages with topic drop are Chinese (Mandarin Chinese; Huang, 1984), German (Ross, 1982; Huang, 1984), Japanese (Hasegawa, 1984–1985), KiNande (Nandi; Authier, 1988), and Spanish (Campos, 1986). Although it has not been established clearly which property of the languages in question allows topic drop, English clearly does not routinely allow it (see also Li and Thompson, 1976; see Tomioka, 2003, for an alternative interpretation of some null arguments in Japanese and in Chinese).

Register Variation

Although the core grammar of English does not routinely allow the deletion of either subjects or objects, both types of deletion are attested in specific registers. Subject deletion is attested in informal variants of spoken English as well as in abbreviated written registers, of which the prototypical illustration is the diary register. Object deletion is typical of various kinds of instructional writing (*see* **Ellipsis**).

Register-Based Subject Omission in English Finite Clauses

Examples The examples in (12) illustrate subject deletion in written English (example (12a) is from a

published diary), and those in (13) illustrate subject deletion in informal spoken English. In these examples, a referential subject is deleted.

(12a) "Dinner rather strained - . . . Ø Went to Wigmore Hall but found the concert was at the Grotian - Ø walked there" (Smart, 1992: 15)
(12b) Ø wish you were here.
(12c) Ø serves four. (recipe)

(13a) Ø wonder what he will do next.
(13b) how much money do you need? Ø can't say really.
(13c) Ø doesn't look too good.

Nonreferential (or 'expletive') subjects can also be deleted. (Sentence (14a) is an attested example from a diary in which the expletive pronoun *it* is deleted; (14b) and (14c) are from the literature on subject deletion.) In (14b), the nonreferential pronoun *it,* which is in construction with a sentence-final clause, is deleted; in (14c), existential *there* is deleted.

(14a) "[Ø] Rained in the night, wind, rain and hail." (Smart, 1995: 27)
(14b) Ø won't be too difficult to reconstruct his argument. (Thrasher, 1977: 44)
(14c) Ø isn't much we can do about it. (Thrasher, 1977: 44)

The Nature of the Understood Subject In the register-specific examples, the deleted subject remains syntactically active. The subject can, for instance, be the antecedent of a reflexive:

(15) Ø walked for hours all by myself.

The register-related variation might at first sight be interpreted as the result of a language-internal resetting of the pro drop parameter, the positive setting of which is responsible for the deletion of the subjects of finite clauses in languages such as Italian. This would mean that while the parameter is set negatively in the core grammar of English, peripheral subsystems might arguably have a positive setting for the parameter. A closer inspection of register-specific subject deletion shows this hypothesis to be empirically inadequate. Subject deletion in English abbreviated registers is more constrained than subject deletion in finite clauses in Italian.

First of all, in the relevant registers in English, finite clauses with deleted subjects must be root clauses, that is, clauses not dominated by another clause. Even in the colloquial or abbreviated register, the following constructed examples in which a subject of an embedded clause is deleted are judged as unacceptable (see also the later discussion of differing judgments for written registers).

(16a) *Think that Ø made a few valiant sallies - . . . *Remember that Ø went to Wigmore Hall - *recall how Ø walked there.
(16b) *Wonder what Ø will do next.
(16c) *Must admit Ø can't say really.
(16d) *Think Ø won't be too difficult to reconstruct his argument.

In root environments, subject deletion is a left-edge phenomenon. It is only allowed when the subject, if present, would have been the leftmost constituent in the root clause:

(17a) *Will Ø see her again?
(17b) *Never have Ø worked so hard at any book.
(17c) ***The next book**, Ø think of calling *Basic grammar.*
(17d) ***Happy with these results**, Ø wasn't.

In pro drop languages, subject deletion is possible in contexts in which English register-related subject deletion is ungrammatical. These contexts include subordinate clauses (10a), root interrogatives (10b), sentences with topicalized arguments (10c), and sentences with topicalized predicates (10d).

The positive setting of the pro drop parameter in Italian and similar languages correlates with a postverbal position being available for a definite subject. In English registers allowing subject deletion, a definite subject cannot occur postverbally (18a). In the registers concerned, the extraction of an interrogative subject across the subordinating conjunction *that* leads to ungrammaticality (18b), whereas such extraction is possible in pro drop languages (4).

(18a) *Has telephoned Louise.
(18b) *Which readers should I expect that – will like my book?

This leads to the conclusion that although the deleted subject in the abbreviated register seems similar to the deleted pronominal subject in Italian finite clauses, the empirical evidence militates against analyzing the phenomenon in terms of a resetting of the pro drop parameter.

An alternative analysis is that the deletion of the subject in the diary register is the result of topic drop. The deletion of referential subjects would offer interpretive support for this point of view because these subjects refer to discourse topics. However, this proposal is problematic because nonreferential subjects can also be deleted (14). Being nonreferential, such subjects cannot be argued to 'refer' to discourse topics (see Haegeman and Ihsane, 2002, and the references cited there). Furthermore, the objects of subordinate clauses may be affected by topic drop (11b), whereas subject deletion is a root clause phenomenon. Finally, English registers displaying subject deletion in finite

Table 1 Conditions on subject deletion

	Core grammar	*Register-specific grammar*
Recovery by subject of adjacent conjunct	+	−
Left-edge constraint	+	+

Table 2 Variable conditions on subject deletion

	Core grammar	*Register 1*	*Register 2*
Recovery by subject of adjacent conjunct	+	−	−
Left-edge constraint	+	+	−

clauses do not display object deletion, which would be surprising if the phenomenon were analyzed as an instantiation of topic drop.

Core Grammar and Periphery: Relaxing the Coordination Constraint on Null Subjects The most promising approach to register-related subject deletion at the moment seems to be to treat the phenomenon in parallel with subject deletion in coordinated finite clauses (see Wilder, 1994). Subject deletion in a coordinated finite clause is subject to two conditions: (1) the deleted subject must be identical to the subject of the immediately preceding conjunct and (2) the deleted subject must be in the left-edge position. Register-related subject deletion can be seen as an extension of left-edge subject deletion in which the requirement of identity with the subject of the first conjunct is abandoned. The difference in the grammatical systems underlying language-internal variation is summarized in Table 1. The register-specific system is characterized by one or more relaxations of conditions of the core grammar. The 'deviant' output resulting from these relaxations belongs to the 'periphery' (Chomsky, 1981).

More Subject Omission Depending on the degree of relaxation of the core conditions of the grammar, the outputs of some register-related grammars will be more 'deviant' than others. The variation in the extent of subject deletion in English finite clauses illustrates how register-related grammars may vary in the degree of deviance of their outputs.

The register of note taking (Janda, 1985) and some recent fictional diary styles display a type of subject omission in English finite sentences that is no longer constrained by the left-edge condition. The following examples are taken from *Bridget Jones's diary*, a fictional diary:

(19a) Was worried that [Ø] might split. (Fielding, 1996: 227)
(19b) Start to wonder whether [Ø] am really good friend. (Fielding, 1996: 261)
(19c) Give all clothes which [Ø] have not worn for two years or more to homeless. (Fielding, 1996: 3)

Many native speakers reject such sentences even for the diary register, in which left-edge null subjects are routinely allowed. But other (mainly British) speakers have started to produce such sentences in the context of abbreviated registers, a mode of writing that has probably developed in the context of electronic communication (see Haegeman and Ihsane, 2002).

Observe that the more liberal subject deletion in these registers does not provide evidence for a resetting of the pro drop parameter. The relevant registers systematically fail to display the other properties associated with the positive setting of the pro drop parameter discussed previously, such as postverbal definite subjects (3) and subject extraction across *that* (4).

The registers with more liberal subject deletion seem to be the product of a further relaxation of the constraints on subject deletion. Subject deletion in the more conservative diary writing is made possible by a grammatical system in which the recovery condition on left-edge ellipsis of subjects has been relaxed but in which the left-edge condition is maintained. Generalized subject deletion in note-taking and recent fictional diary writing is the output of a subsystem in which the left-edge constraint on ellipsis has also been relaxed (see Table 2).

Other Register-Related Peripheral Phenomena

Object Deletion and Instructional Writing As is the case for subject deletion, object deletion is not routinely allowed in English. Still, the phenomenon is attested in specific registers. The most obvious illustration is recipes, in which objects that are contextually recoverable are routinely deleted. The phenomenon is also found in other types of instructional writing:

(20a) Peel and slice apples thinly. Sprinkle Ø with ½ teaspoon salt and rub Ø in with hands. Chop the coriander leaves coarse. Mix everything together and stir Ø well. Set Ø aside for 30 minutes after mixing Ø.
(20b) Serve Ø chilled.
Handle Ø with care.
Keep Ø away from children.

In the recipe text in (20a), the deleted direct object, represented by Ø, is recovered from the immediate context. In the instructions in (20b), the referent of the understood direct object is located in the nonlinguistic context: it is the item on which the text is

written. The object deletion illustrated in such examples might be analyzed as a kind of topic drop, as discussed previously. But, again, register-related object deletion is not the same phenomenon as topic drop. Register-related object deletion seems to be restricted to imperative sentences, which lack an overt subject. In finite sentences with overt subjects, object deletion becomes ungrammatical (Massam, 1989; Massam and Roberge, 1989). No such constraint governs topic drop; see (11).

(21a) You peel and slice the apples thinly. *You sprinkle Ø with ½ teaspoon salt and rub Ø in with hands. You chop the coriander leaves coarse. *You should mix everything together and stir Ø well. *You should set Ø aside for 30 minutes after mixing Ø.
(21b) *You must serve Ø chilled.
*You should handle Ø with care.

Omission of *be* Subject omission and object omission are not the only instances of register-related ellipsis. It has been noted that function verbs such as copula *be* and auxiliary *be* are often left unexpressed in specific abbreviated registers, such as diary writing or newspaper headlines.

(22a) John in hospital.
(22b) Mary working on a new book.
(22c) Prime Minister accused by feminists.

Although in a number of languages the copula may indeed be absent (e.g., Hebrew and Russian; Doron, 1983; Greenberg, 2002), copula ellipsis is not routinely available in English finite clauses. Compare English (23b) with the Hebrew example in (23a) (Greenberg, 2002: 268):

(23a) Rina xaxama
Rina wise.
'Rina is wise'
(23b) *Rina wise.

On the other hand, both the copula *be* and auxiliary *be* can be absent in nonfinite contexts in English:

(24a) With [John in hospital], we cannot do the show as planned.
(24b) With [Mary working on a new book], things are difficult.

In (24) the preposition *with* is associated with a complement in which a predication relation is established between a subject and a predicate without there being an overt linker. In the core grammar of English, this pattern is restricted to nonfinite contexts. The grammar of English abbreviated registers and headlinese seems to be characterized by a relaxation of the constraint on *be* omission; as a result of this, it can be extended to root clauses.

Determiner Ellipsis in Headlinese English headlines display the phenomenon of article deletion. The following is from Stowell (1997).

(25a) Old man finds rare gold coin.
'An old man has found a rare gold coin.'

This type of deletion is, again, not unconstrained. Stowell (1997) showed that there is a right to left dependency, in that a NP may lack an article provided that NPs to the left of it also lack the article.

(25b) An old man finds a rare gold coin.
(25c) *An old man finds rare gold coin.

Stowell showed that, in configurational terms, what is at stake is not a left to right relation but a c-command relation (*see* **Command Relations, X-Bar Theory**).

Register Specific Adult Grammars and Language Acquisition

Abbreviated registers of English, such as headlinese, diary writing, recipe texts, and instructional writing, are characterized by a marked increase in the application of deletion, giving rise to utterances that are not acceptable in the neutral register but that are routinely attested in the specialized registers. Apart from the intrinsic interest of the empirical data, the study of the grammatical properties of the abbreviated registers is also relevant to the study of language acquisition. The high degree of ellipsis found in English abbreviated registers finds an analog in the ellipsis that characterizes the early production of children acquiring English as a first language. Example (26a) illustrates ellipsis of the auxiliary *be*, (26b) illustrates determiner ellipsis, and (26c) illustrates subject ellipsis in the speech of young children.

(26a) Lois coming (Kathryn, 21 months; Radford, 1990: 71)
(26b) Paula play with ball (Paula, 18 months; Radford, 1990: 72)
(26c) Want paint (Ludy, 20 months, Radford, 1990: 216)

There is a vast literature on the nature of the early language production of children and on the question of how it should be related (if at all) to the target adult system. In one line of research, an attempt is made to maximize the relation between the early production of children and the adult grammar. This approach explores the similarity between the early production of children and the output of the register-related adult grammar (see Hyams and Wexler, 1993; Friedemann and Rizzi, 1999). The child grammar could be seen as

exploiting a range of options that, although unavailable in the core grammar of the language, are available in register-related periphery.

'Variety' Labeling in English Monolingual Dictionaries

'Register' is one of a number of terms used by British and American lexicographers to denote a particular kind of limitation on the use of a word or phrase. This article will describe the ways in which the term is, or has been, understood, and indicate how it functions in various dictionaries as part of a scheme of labels by means of which various types of usage restriction are indicated. The focus will be chiefly on British learners' dictionaries of the 1970s and later.

The first systematic attempt by British dictionary makers to define 'register' for language-teaching purposes, including EFL dictionary making, was made in the early 1960s. The definition of 'register' and related key terms owed much to a group of Edinburgh linguists who were attempting at the time to elaborate a theory of language varieties (Halliday *et al.*, 1964). The term 'register', however, had been defined in a linguistic sense earlier, in 1956. The subentry in the *Oxford English Dictionary* (*OED*2, 1989) is as follows:

register, *n.*[1]

d. *Linguistics*. A variety of a language or a level of usage, *spec*. one regarded in terms of formality and choice of vocabulary, pronunciation, and (when written) punctuation, and related to or determined by the social role of the user and appropriate to a particular need or context.

In the words 'a level of usage, *spec*. one regarded in terms of formality' and 'determined by the social role of the user' can be seen support for one particular meaning of the term. This is illustrated by a quotation from the linguist G. N. Leech (dated 1966), which states that "varieties of English distinguished by use in relation to social context are called *registers*" (*OED*2, 1989). This is not, however, the sense in which the term was used by Halliday and his colleagues. For them, 'register' was an inclusive term that referred to variation in language that was attributable to **any** situational factor, and not social role alone. "Language varies as its function varies; it differs in different situations. The name given to a variety of language distinguished according to use is 'register'" (Halliday *et al.*, 1964: 87). The group then went on to recognize three subcategories of register: (a) 'field of discourse,' including technical subjects such as biology or mathematics; (b) 'mode of discourse,' the written or spoken medium of the language activity; and (c) 'style of discourse,' or the relations between the participants. (Here we are back with the *OED* definition of 'register.')

Some confusion was introduced by another Edinburgh colleague, J. C. Catford, who followed his colleagues in his use of 'style' and 'mode,' but idiosyncratically used 'register' to signify 'variety related to the wider social role being played . . . at the moment of utterance' (Catford, 1965: 85). Moreover, as another quotation (dated 1977) from the same *OED* entry suggests, Peter Strevens moved in a different direction: "they probably know the term *register* – a variety related to a particular use of the language, a particular subject or occupation" (s.v. 'register', *OED*2), where 'a particular use of the language' is vague and where 'a particular subject or occupation' suggests that a register is a language variety related to a technical or occupational area or field. This use was to influence later dictionary practice, as was the original *OED* sense.

Register in the Learners' Dictionaries of the 1970s

The labeling scheme in the *Oxford Advanced Learner's Dictionary* (*OALD*) continued to have shortcomings in the early 1970s inherited from earlier editions. This can be shown by examining the list of labels and abbreviations on the inside cover of *OALD*3 (1974). These were given the headings 'stylistic values' (cf. Halliday *et al.*, 1964) and 'specialist English registers,' where it will be noted that 'register' is given the meaning later ascribed to it by Strevens. (Here are listed such specific technical fields as 'aerospace,' 'finance,' and 'engineering.') Under the heading 'stylistic values' were included 'formal' and 'colloquial' (cf. 'informal'), which were arguably particular values along a scale of register (Cowie, 1999: 165; cf. Stein, 1979: 5).

The compilers of the *Longman Dictionary of Contemporary English* (*LDOCE*, 1978) developed a broad framework of highly specific category labels to be attached to words that were in some way restricted in their use. These included terms relating to technical field (thus, 'law,' 'medicine'), and the kinds of occasion on which the words might be used (thus, 'fml,' 'infml'). There is, though, no mention of the general categories (such as 'field' or 'register') to which such specific designations might belong.

Register and Field Labeling in Dictionaries of the 1980s

Those more general categories were more clearly identified in dictionaries of the late 1980s, particularly in *LDOCE*2 (1987) and *OALD*4 (1989). In the 'full guide to using the dictionary' in *LDOCE*2, sets of related specific labels are drawn together under a description of what they have in common. There are, though, no general labels as such:

> Labels showing situations in which words are used . . .
> *infml* informal . . .
> *fml* formal . . .
> *sl* slang (*LDOCE*2, 1987: F46).

In *OALD*4 five major categories are distinguished according to use. However, each category is given an appropriate general label: 'currency,' 'region,' 'register,' 'technical field,' and 'evaluation' – relating respectively to date of use, country or area of use, special relationship between speakers, use in a specialist field, and speaker attitude. Here, it will be seen, 'register' reverts to its original sense.

Introduction

Native speakers of a language choose among different words and grammatical structures depending on the communicative situation. For example, we do not use the same words and structures to write an academic term paper that we would use when talking to a close friend about weekend plans.

Researchers study the language used in a particular situation under the rubric of 'register.' 'Register' is used here as a cover term for any language variety defined by its situational characteristics, including the speaker's purpose, the relationship between speaker and hearer, and the production circumstances.

Speech and writing can be considered as two very general registers. The most obvious difference between the two is the physical mode of production. In addition, spoken discourse is often interactive and speakers often do not plan their language ahead of time. In contrast, written discourse is usually not interactive. In fact, writers are usually addressing a large audience, rather than a single reader. However, writers can plan and revise the text as much as they want. The final written text includes only the revised and edited language (*see* **Pragmatics of Reading**).

At the same time, there are many more specified spoken registers. For example, a formal lecture is very different from conversation: it is carefully planned ahead of time, it is addressed to a large audience, it will probably not be interactive, and the speaker will usually want to communicate information about the world rather than telling us a lot about him- or herself. Similarly, there are many specific written registers. For example, e-mail messages are very different from textbooks: e-mails are not always edited or revised carefully; they probably will be written to a single person, who will respond; and they may talk about the personal feelings and activities of the writer (*see* **E-mail, Internet, Chatroom Talk: Pragmatics**).

Different cultures recognize different registers. One way to figure out the registers in a culture is to list the text categories that have names, such as 'letters,' 'textbooks,' 'e-mail messages,' 'newspaper articles,' 'biographies,' 'shopping lists,' 'term papers,' 'novels,' and

Register and Field Labeling in Dictionaries of the 1980s

Those more general categories were more clearly identified in dictionaries of the late 1980s, particularly in *LDOCE*2 (1987) and *OALD*4 (1989). In the 'full guide to using the dictionary' in *LDOCE*2, sets of related specific labels are drawn together under a description of what they have in common. There are, though, no general labels as such:

> Labels showing situations in which words are used . . .
> *infml* informal . . .
> *fml* formal . . .
> *sl* slang (*LDOCE*2, 1987: F46).

In *OALD*4 five major categories are distinguished according to use. However, each category is given an appropriate general label: 'currency,' 'region,' 'register,' 'technical field,' and 'evaluation' – relating respectively to date of use, country or area of use, special relationship between speakers, use in a specialist field, and speaker attitude. Here, it will be seen, 'register' reverts to its original sense.

Introduction

Native speakers of a language choose among different words and grammatical structures depending on the communicative situation. For example, we do not use the same words and structures to write an academic term paper that we would use when talking to a close friend about weekend plans.

Researchers study the language used in a particular situation under the rubric of 'register.' 'Register' is used here as a cover term for any language variety defined by its situational characteristics, including the speaker's purpose, the relationship between speaker and hearer, and the production circumstances.

Speech and writing can be considered as two very general registers. The most obvious difference between the two is the physical mode of production. In addition, spoken discourse is often interactive and speakers often do not plan their language ahead of time. In contrast, written discourse is usually not interactive. In fact, writers are usually addressing a large audience, rather than a single reader. However, writers can plan and revise the text as much as they want. The final written text includes only the revised and edited language (*see* **Pragmatics of Reading**).

At the same time, there are many more specified spoken registers. For example, a formal lecture is very different from conversation: it is carefully planned ahead of time, it is addressed to a large audience, it will probably not be interactive, and the speaker will usually want to communicate information about the world rather than telling us a lot about him- or herself. Similarly, there are many specific written registers. For example, e-mail messages are very different from textbooks: e-mails are not always edited or revised carefully; they probably will be written to a single person, who will respond; and they may talk about the personal feelings and activities of the writer (*see* **E-mail, Internet, Chatroom Talk: Pragmatics**).

Different cultures recognize different registers. One way to figure out the registers in a culture is to list the text categories that have names, such as 'letters,' 'textbooks,' 'e-mail messages,' 'newspaper articles,' 'biographies,' 'shopping lists,' 'term papers,' 'novels,' and

so on. However, registers can be defined at any level of generality, and more specialized registers may not have widely used names (see Biber, 1994). For example, 'academic prose' is a very general register, whereas 'methodology sections in experimental psychology articles' is a much more highly specified register.

Registers differ in their situational characteristics. They are planned to different extents, interactive to different extents, and addressed to different kinds of audiences. They also have different topics, and they are written with different goals or purposes.

Registers are identified by 'nonlinguistic' or 'situational' characteristics, such as the setting, the audience, interactiveness, and extent of planning. There have been numerous studies that describe the situational parameters that distinguish among registers (see, e.g., Crystal and Davy, 1969; Hymes, 1974; Brown and Fraser, 1979; Duranti, 1985; Biber, 1994). Several situational characteristics are identified in most of these frameworks, including the participants (including their relationships and their attitudes toward the communication); the setting (including factors such as the extent to which time and place are shared among participants and the level of formality); the channel (or mode) of communication; the production and processing circumstances; the purpose of communication; and the topic. A register can be defined by a particular combination of values for any (group) of these situational characteristics (*see* **Situation Semantics**).

Although registers are defined in situational terms, they can also be described in terms of their typical linguistic characteristics. This is because linguistic features serve important communicative functions and therefore tend to occur in registers with certain situational characteristics. For example, first- and second-person pronouns (*I* and *you*) are especially common in conversation. These linguistic features are associated with the normal situational characteristics of conversation: speakers in conversation talk a great deal about themselves, and so they use the pronoun *I* a lot. They are also interactive, talking to another individual person, and so they also use the pronoun *you* a lot (*see* **Pronouns**).

There are many studies that describe both the situational and linguistic characteristics of a particular register. These are often highly specialized registers, such as sports announcer talk (Ferguson, 1983), note-taking (Janda, 1985), personal ads (Bruthiaux, 1994), and classified advertising (Bruthiaux, 1996). Many register studies have also been carried out within a Hallidayan functional–systemic framework (see, e.g., Halliday, 1988, and the collection of papers in Ghadessy, 1988, which include descriptions of written sports commentary, press advertising, and business letters) (*see* **Halliday, Michael A. K. (b. 1925)**). Several studies adopting this approach have been concerned with school-based registers and their implications for education generally (see, e.g., Martin, 1993). The academic journal *English for Specific Purposes* publishes articles that describe the characteristics of specialized registers, providing the foundation for more focused curricula for the teaching of English as a Foreign Language (*see* **Languages for Specific Purposes**).

In addition to the study of individual registers, many studies have made comparisons across registers, studying the patterns of 'register variation.' Register variation is inherent in human language: a single speaker will make systematic choices in pronunciation, morphology, word choice, and grammar, reflecting a range of situational factors. The ubiquitous nature of register variation has been noted by a number of scholars, such as Ure: "each language community has its own system of registers . . . corresponding to the range of activities in which its members normally engage" (1982: 5); Ferguson: "register variation, in which language structure varies in accordance with the occasions of use, is all-pervasive in human language" (1983: 154); or Hymes: "no human being talks the same way all the time . . .. At the very least, a variety of registers and styles is used and encountered" (1984: 44).

Comparative register analyses are important for two major arenas of linguistic research: (1) linguistic descriptions of lexical and grammatical features, and (2) descriptions of the registers themselves. With respect to traditional lexical and grammatical descriptions, register studies have shown that functional descriptions of a grammatical feature are generally not valid for the language as a whole. Rather, characteristics of the textual environment interact with register differences, so that strong patterns of use in one register often represent only weak patterns in other registers. For register descriptions, a comparative register perspective provides the baseline needed to understand the linguistic characteristics of any individual register.

Register differences can exist at any linguistic level. The following sections discuss some of these differences at the lexical, grammatical, and lexico-grammatical levels. Then, I return to the description of registers and the overall patterns of register variation.

Lexical and Grammatical Differences among Registers

One analytical approach that has been especially productive for studying register variation is corpus-based analysis, with its emphasis on the representativeness

of the database, and its computational tools for investigating distributional patterns across registers and across discourse contexts in large text collections (see McEnery and Wilson, 1996; Biber *et al.*, 1998; Kennedy, 1998; Meyer, 2002; and Hunston, 2002 for introductions to this analytical approach) (*see* **Corpus Linguistics**). The *Longman grammar of spoken and written English* (LGSWE; Biber *et al.*, 1999) applies corpus-based analyses to show how any grammatical feature can be described for both its structural characteristics and its patterns of use across spoken and written registers. The analyses in the LGSWE are based on texts from four registers: conversation, fiction, newspaper language, and academic prose. Although these are general registers, they differ from one another in important ways (e.g., with respect to mode, interactiveness, production circumstances, purpose, and target audience). The analyses were carried out on the Longman Spoken and Written English (LSWE) Corpus, which contains ca. 40 million words of text overall, with ca. 4–5 million words from each of these four registers. Selected analyses from the LGSWE are used in the following sections to illustrate the systematic lexical and grammatical differences found across registers.

Lexical Differences across Registers

Probably the most obvious linguistic difference among registers is word choice. For example, in conversation we rely heavily on vague nouns with general content – such as *stuff* and *thing* – whereas these nouns are rarely used in registers such as textbooks or newspaper editorials.

In fact, the most common words in each word class show sharp differences among registers. Table 1 shows some of the contrasts between the common verbs, adjectives, and adverbs used in conversation versus the words belonging to the same lexical categories used in academic prose.

Similar differences could easily be identified for other registers. In part, these differences reflect the different topics and communicative purposes typically associated with a register. However, these differences can also reflect conventional associations of particular words with particular situations of use.

Grammatical Differences across Registers

Although they are not as easily noticed, grammatical differences among registers are as pervasive as lexical differences. The descriptions in the LGSWE show that nearly any grammatical feature will be distributed in systematic ways across registers. Tables 2 and 3 contrast some of the most important distinctive grammatical characteristics of conversation versus academic prose.

Table 1 Selected common verbs, adjectives, and adverbs in conversation versus academic prose

Conversation	*Academic prose*
Verbs	
Get	Produce
Go	Provide
Come	Obtain
Make	Form
Take	Describe
Say	Develop
Know	Require
Think	Occur
See	Involve
Want	Include
Adjectives	
Big	Same
Little	Different
Old	Important
Good	Necessary
Nice	Difficult
Sure	Possible
Right	Likely
Adverbs	
Just	Often
Really	Usually
Too	Especially
Pretty	Relatively
Real	Particularly
Like	Generally
Maybe	Indeed

Source: Based on LGSWE (Biber *et al.*, 1999: 512–513, 517, 561–562).

Many of the grammatical features typical of conversation listed in Table 2 reflect a heavy reliance on verbs, adverbs, and pronouns instead of complex noun phrases. These features result in the dense use of short, simple clauses. However, it also turns out that several dependent clause features are much more common in conversation than other registers. These are mostly complement clauses controlled by verbs, especially *that*-clauses (the complementizer *that* is frequently omitted in these structures). These features are often used to express 'stance' in conversation: the controlling verb expresses the stance, and the complement clause contains the new information, for example, *I just think [it's cool]* or *I know [what you're talking about]*.

The typical characteristics of conversation can be contrasted with the typical features of academic prose. Three different word classes are especially prevalent in academic prose: nouns, adjectives, and prepositions. Overall, these grammatical classes are more frequent in academic prose than in other registers, but there are many related specific features that are especially characteristic of academic prose (e.g.,

Table 2 Grammatical features that are especially common in conversation

Feature	*Pattern of use*
Verbs and verb phrases	
Verbs, overall	Verbs are much more common in conversation than in informational written registers (almost 1/3 of all content words in conversation are lexical verbs) (p. 65, 359)
Mental verbs	Mental verbs (e.g., *know, think, see, want, mean*) are more common in conversation (p. 366, 368)
Modal verbs	Modal verbs are also much more common in conversation than in the written registers, especially *can, will, would* (p. 486 ff.); semimodal verbs (such as *especially, have to*, (*had*) *better*, (*have*) *got to, used to*) are common only in conversation (p. 486 ff.)
Tense and aspect	ca. 70% of all verb phrases in conversation are present tense (p. 456 ff.); the progressive aspect (verb + *-ing*) is common in conversation (and fiction) (p. 462 ff.)
Adverbs	
Simple adverbs	Most common in conversation (pp. 540–542)
Adjectives used as adverbs	Common only in conversation, e.g., *It's running real good* (pp. 542–543)
Adverbs of 'stance'	Most common in conversation, especially *really, actually, like, maybe* (pp. 859, 867–871)
Pronouns	
Personal pronouns	Most common in conversation, especially *I, you, it* (pp. 92, 235, 237, 333–334)
Demonstrative pronoun *that*	Extremely common only in conversation (pp. 349–350)
Simple clauses	
Questions	Common only in conversation (p. 211 ff.)
Imperatives	Common only in conversation (pp. 221–222)
Coordination 'tags'	Common only in conversation, e.g., *or something* (but note the use of *etc.* in writing) (pp. 116–117)
Dependent clauses	
Verb + *that*-clause	Most common in conversation, especially *think, know, guess*, + *that*-clause (pp. 668–670, 674–675); overall, over 80% of all *that*-clauses in conversation omit *that* (pp. 680–683)

Source: Based on a survey of LGSWE (Biber *et al.*, 1999). Page numbers refer to specific pages in the LGSWE.

nominalizations, noun phrases with multiple modifiers). In contrast, verbs overall are much less common in academic prose than in other registers, although there are specific verb categories that are especially common in academic prose (e.g., copula *be*, existence verbs, derived verbs, and passive voice verbs). Similarly, there are specific categories of adverbs and adverbials (e.g., linking adverbials) that are especially common in academic prose. Table 3 lists some of the major grammatical features that are especially common in academic prose.

A comparison of the typical linguistic characteristics of conversation and academic prose reveals several unanticipated differences, showing how empirical register analyses can run counter to our prior expectations. One of the most surprising differences relates to the use of dependent clauses, contradicting the widespread belief that academic prose is more 'complex' than conversation and that dependent clauses are therefore especially common in academic prose. Rather, empirical register studies have shown that only some dependent clause types are common in written registers and that specific clause types have their own distributions among registers. For example, finite relative clauses are much more common in writing than in conversation, but they are most common in newspaper writing and fiction rather than in academic prose. However, relative clauses with the relative pronoun *which* are most frequent in academic prose. Nonfinite relative clauses (*-ing* clauses and *-ed* clauses) are also most common in academic prose (although they are frequently found in newspaper writing as well) (*see* **Media: Pragmatics**).

Other dependent clause types turn out to be more common in speech. For example, many complement clause types are much more common in conversation than in academic prose (see Table 2). These complement clauses often serve important stance functions in conversation (e.g., *I think that…; I don't know what…; I want to…*), making them an especially frequent and important part of everyday interactions. Only one major type of complement clause is especially characteristic of academic prose: extraposed clauses controlled by adjectives (e.g., *It is possible that…, It is important to…*). Adverbial clauses have a different distribution across registers, being most common overall in fiction. However, conversation also uses adverbial clauses to a slightly greater extent than academic prose (and conditional clauses are especially common in conversation). Only one subtype of adverbial clause is especially frequent in academic prose: concessive clauses.

Table 3 Some grammatical features that are especially common in academic prose

Feature	*Pattern of use*
Nouns and noun phrases	
Nouns, overall	Approximately 60% of all content words in academic prose are nouns (p. 65)
Pronouns	Nouns are much more common than pronouns in academic prose, especially in object positions (pp. 235–236); as to specific pronouns, such as *this* and generic *one*, they are much more common in academic prose (pp. 349–350, 354–355); *this* is used for immediate textual reference, whereas *one* is used for generic rather than specific reference
Plural nouns	Much more common in writing than in conversation; most common in academic prose (pp. 291–292)
Nominalizations	Much more common in academic prose, especially nouns formed with -*tion* and -*ity* (pp. 322–323)
Definite article *the*	Much more common in writing than in conversation; most common in academic prose (pp. 267–269)
Demonstratives	Most common in academic prose; especially *this* and *these* (p. 270, 274–275)
Modifiers	60% of all noun phrases in academic prose have a modifier (p. 578)
Adjectives	
Adjectives, overall	Adjectives are much more common in academic prose than in conversation or fiction (pp. 65, 506)
Attributive adjectives	Much more common in academic prose (pp. 506, 589)
Derived adjectives	Much more common in academic prose, especially adjectives formed with -*al* (pp. 531–533)
Verbs and verb phrases	
Copular verbs *be, become*	Most common in academic prose (pp. 359–360, 437–439)
Existence verbs	Much more common in writing than in conversation; most common in academic prose (e.g., *include, involve, indicate*) (pp. 366, 369, 419)
Verbs with inanimate subjects	Common only in academic prose (e.g., *this quotation shows; the test sequence proves*) (pp. 378–380)
Derived verbs	Most common in academic prose, especially verbs formed with *re*- and -*ize* (pp. 400–403)
Passive voice	Much more common in academic prose, especially the 'short' passive (without *by*-phrase) (pp. 476–480, 937–940)
Adverbs and adverbials	
Linking adverbials	Most common in academic prose, especially *however, thus, therefore, for example* (e.g.) (pp. 766, 880–882)
Purpose and concessive adverbials	Most common in academic prose (*in order to, so as to, even*, *(al)though, albeit*, etc.) (pp. 784, 786, 820–821, 824–826)
Dependent clause features	
Relative clauses with the relative pronoun *which*	Most common in academic prose (pp. 609–612)
Noun + *that*-complement clause	Most common in academic prose (e.g., *the fact that* . . .); frequent head nouns are *fact, possibility, doubt, belief, assumption* (pp. 647–651)
Abstract noun + of + *ing*-clause	Most common in academic prose (e.g., *methods of assessing error*); frequent head nouns are *way, cost, means, method, possibility, effect, problem, process, risk* (pp. 653–655)
Extraposed clauses	Most common in academic prose, especially *that*-clauses controlled by the adjectives *clear*, (*un*)*likely*, and (*im*)*possible* (e.g., *it is likely that* . . .), and *to*-clauses controlled by adjectives (e.g., *it is important to* . . .) (pp. 672–675)
ing-clauses controlled by adjectives	Most common in academic prose (e.g., *capable of, important for/in, useful for/in*) (p. 749)
Concessive adverbial clauses	Most common in academic prose (and newspapers) (pp. 820–825)
Other features	
Prepositions	Most common in academic prose (p. 92)
Of-phrases	Much more common in writing than in conversation; most common in academic prose (pp. 301–302)
Stance noun + *of*-phrase	Most common in academic prose, especially *possibility of, value of, importance of, problem of, understanding of* (pp. 984–986)
Dual-gender reference	Common only in academic prose (*he or she, his or her, he/she*) (pp. 316–317)

Overall Patterns of Register Variation: The MD Approach

As noted above, a complementary research goal is to describe the general characteristics of a register and the overall patterns of register variation in a language. Despite the fundamental importance of register variation, there have been few comprehensive analyses of the register differences in a language. This gap is due mostly to methodological difficulties: until recently, it has not been feasible to analyze the full

range of texts, registers, and linguistic characteristics required for comprehensive analyses of register variation. With the availability of large on-line text corpora and computational analytical tools, such analyses have become possible. (*see* **Computational Lingustics: Overview**).

The multidimensional (MD) analytical approach was developed for the comprehensive analysis of register variation, to discover and interpret the patterns of linguistic variation among registers in a corpus of texts (see, e.g., Biber, 1988). Early researchers in sociolinguistics (e.g., Ervin-Tripp, 1972; Hymes, 1974) argued that linguistic features work together in texts as constellations of co-occurring features (rather than as individual features) to distinguish among registers. Although this theoretical perspective is widely accepted, linguists lacked the methodological tools required to identify these co-occurrence patterns before the availability of corpus-based analytical techniques. MD analysis provides these tools, using automatic corpus analysis to analyze the quantitative distribution of numerous linguistic features across the texts and text varieties of a corpus and multivariate statistical techniques (especially factor analysis) to identify the co-occurrence patterns among features.

The dimensions identified in MD analysis have a linguistic basis, but they are interpreted functionally. The linguistic dimension exhibits a group of features (e.g., nouns, attributive adjectives, prepositional phrases) that co-occur with a markedly high frequency in texts. These co-occurrence patterns are interpreted to assess their underlying situational, social, and cognitive functions. For example, the frequent co-occurrence of first-person pronouns, second-person pronouns, hedges, and emphatics in conversational texts is interpreted as reflecting directly interactive situations and a primary focus on personal stance and involvement (*see* **Mitigation**).

Biber (1988) identified five main dimensions of variation in a general corpus of spoken and written registers. He used factor analysis to identify the groups of linguistic features associated with each dimension (i.e., the linguistic features that co-occur in texts with markedly high frequencies). The co-occurring groupings of features on each dimension reflect distinct functional relations, indicated by the interpretive labels for each one: *Involved versus informational production, Narrative discourse, Situation-dependent versus elaborated reference, Overt expression of persuasion*, and *Impersonal style*. Biber (1988: Chap. 6–7; 1995: Chap. 5–7) and Conrad and Biber (2001: Chap. 2) provided detailed justification for these interpretations based on the shared communicative functions of the co-occurring linguistic features on each dimension plus the distribution of registers along each dimension.

MD analyses of register variation in English have been carried out by numerous researchers focusing on a wide range of specific research questions. The papers by Atkinson, Burges, Connor-Linton, Conrad, Helt, Shohamy, Reppen, and Rey (all included in Conrad and Biber, 2001) provide a sampling of MD studies by U.S.-based scholars.

Early MD studies investigated the synchronic relations among spoken and written registers in English (e.g., Biber, 1988), whereas later studies focused on diachronic register variation (e.g., Biber, 1995; Biber and Finegan, 1989a), more specialized discourse domains (e.g., Biber *et al.*, 2002; Conrad, 1996, 2001; Connor and Upton, 2003), and the patterns of register variation in other languages (e.g., Kim and Biber, 1994 on Korean; Biber and Hared, 1992 on Somali). Biber (1995) synthesized these studies to investigate the extent to which the underlying dimensions of variation and the relations among registers are configured in similar ways across languages.

Conclusion

This article has surveyed the kinds of situational and linguistic differences that distinguish among registers. Registers differ with respect to a wide array of situational characteristics, relating to purpose, topic, physical setting, production circumstances, and the relations among participants. These situational differences are associated with important linguistic differences at the lexical, grammatical, and lexicogrammatical levels. Furthermore, corpus-based analytical techniques can be employed to identify the linguistic co-occurrence patterns that regularly occur in texts from different registers, providing the basis for comprehensive analyses of register variation.

All language users adapt their language to different situations of use. It would be nearly impossible to spend an entire day using only one register – only having casual conversations, or only reading a newspaper, or only writing an academic paper. Rather, switching among registers is as natural as human language itself. Consequently, the study of register variation is not a supplement to the description of grammar, discourse, and language use; rather, it is central to these enterprises.

Gladys Amanda Reichard was born in Bangor, Pennsylvania on July 17, 1893. Raised in a Quaker household that valued education, she taught elementary school for six years before entering college. Reichard's passion for language became clear even in her undergraduate years at Swarthmore College, where she studied Latin and classics, completing her B.A. in 1919. That same year, she enrolled in the doctoral program in anthropology at Columbia University, where she began her studies in Native American languages under the direction of the eminent early Americanist, Franz Boas. After completing her masters degree in 1921, Reichard began her teaching career at Barnard College the same year, a

Reichard, Gladys A. (1893–1955)

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Gladys Amanda Reichard was born in Bangor, Pennsylvania on July 17, 1893. Raised in a Quaker household that valued education, she taught elementary school for six years before entering college. Reichard's passion for language became clear even in her undergraduate years at Swarthmore College, where she studied Latin and classics, completing her B.A. in 1919. That same year, she enrolled in the doctoral program in anthropology at Columbia University, where she began her studies in Native American languages under the direction of the eminent early Americanist, Franz Boas. After completing her masters degree in 1921, Reichard began her teaching career at Barnard College the same year, a

position she kept until her death in 1955. In 1923, Reichard completed her doctorate in anthropology under the guidance of her mentor, Pliny Earle Goddard, himself the first person to earn a doctorate in linguistics in the United States (at UC Berkeley in 1904). In 1951, Reichard was promoted to the rank of full professor at Barnard College. She is best known for her descriptive studies of Native American languages, and for her groundbreaking work on Navaho (Navajo) language and culture.

In the summer of 1922, Reichard traveled to northwestern California, where she cut her teeth as a linguist by writing a descriptive grammar of Wiyot, a highly endangered language remembered by only a handful of speakers at the time. Initially, Reichard's interest in Wiyot was piqued by Sapir's controversial proposal that Wiyot may be related to the Algonquian languages of the Plains and American northeast, a hypothesis that demanded solid linguistic evidence. With support from the Anthropology department at the University of California, Berkeley, Reichard completed her fieldwork by the spring of 1923, publishing the results in her 1925 monograph, *Wiyot grammar and texts*. Considering that modern phonemics had not yet been conceived, Reichard's treatment of Wiyot phonology is surprisingly accurate, presenting both a fair portrait of the phonetic inventory and a sensitive treatment of rules for combining sounds, such as assimilation and elision. Throughout the grammatical sketch, Reichard copiously illustrates all stems and affixes with the paradigms she elicited from informants, a characteristic later found in all of her linguistic work. True to the cultural model advocated by the early Boasian linguists, Reichard devoted equal attention to Wiyot vocabulary and narrative, compiling a 30-page dictionary and collecting nearly 50 texts on traditional folklore and mythology. Today, Reichard's book continues to be of value to linguists and community members striving to revitalize the language. Unfortunately, even Reichard's meticulous study did not resolve the Algonquian question at the time, a problem that was not adequately addressed for decades to come (see Haas, 1958). On the strength of her descriptive grammar, Reichard was awarded her Ph.D. in 1923.

After teaching for several years at Barnard College, Reichard returned to the field to document the Coeur d'Alene language of Idaho over the summers of 1927 and 1929. Her mentor, Boas, who was eager to include a sketch of Coeur d'Alene in his *Handbook of American Indian languages* (Reichard, 1938), secured generous support for both trips. Upon arrival on the reservation, Reichard was fortunate to encounter a consultant named Dorothy Nicodemus, one of the few surviving monolinguals. Nicodemus's daughter-in-law, Julia, provided translations. To Reichard's great fortune, Dorothy's grandson, Lawrence Nicodemus, had a rare gift for analyzing the grammatical categories of Coeur d'Alene, his native language, which Reichard recognized and encouraged. With assistance from these gifted consultants, Reichard assembled the materials for a grammatical sketch and collection of narrative texts, which she published in 1938 and 1947, respectively.

The following summer, Reichard embarked on an ambitious research project aimed at documenting the traditional Navaho religious life. She sought to conduct the study purely in the Navajo language, for the sake of capturing the fine shades of meaning so easily lost in translation, especially when relying on interpreters. Starting in 1930, Reichard began living with a Navaho family during the summers, where she could immerse herself in the language around the clock, while attending local religious ceremonies. By 1939, she had lived in this family setting for over three years total, while also teaching writing to adult speakers at the Hogan School on the reservation. By immersing herself in the language, Reichard sought to distinguish herself from other linguists of her era, such as Sapir and Hoijer, whom she sharply criticized for not speaking their field languages fluently in a natural cultural setting. Yet, like Sapir and Boas, Reichard also encouraged native speakers to begin the process of documenting their native languages on their own, often incorporating native observations into her own studies.

Reichard's sustained work among the Navajo, which she continued for over a decade, led to the crowning achievements of her career, namely, the publication of her 2-volume ethnographic masterpiece, *Navajo religion: a study in symbolism* in 1950, followed by her authoritative reference *Navajo grammar* in 1951. Throughout *Navajo religion*, Reichard drew extensively on native terminology to clarify key concepts in traditional life, providing detailed translations of actual Navajo words for ceremonies, mythical personages, illnesses, and symbols, with supplementary examples from stories, songs, and religious narratives. Her grammar, which was meant to accompany the ethnography, began with a sensitive treatment of tone and morphophonemic processes, before progressing to a sophisticated analysis of the verb template, a formidable challenge even in terms of contemporary linguistics. Throughout the grammar, Reichard illustrated her observations with many detailed examples and paradigms while concluding the work with lengthy sections on syntax and usage, which were rare before the 1960s. As a byproduct of her work on Navajo vocabulary, Reichard also left an unpublished manuscript on file at the archives of the

University of Northern Arizona, which contained the outline of an ethnographic dictionary.

Reichard remained exceptionally active in service over the course of her career, taking secretarial positions with several major professional organizations, including the American Ethnological Society (1924–1926), the American Folklore Society (1924–1926), and the New York Linguistic Circle (1945–1947). In 1940, she accepted a position as the interim editor of the *Journal of American Folklore*, and in 1945 she served on Section H of the American Association for the Advancement for Sciences.

Reichenbach, Hans (1891–1953)

L C Badon and J W Oller Jr, University of Louisiana at Lafayette, Lafayette, LA, USA

© 2006 Elsevier Ltd. All rights reserved.

Hans Reichenbach was born on September 26, 1891, in Hamburg, Germany, and died on April 9, 1953, in Los Angeles. His mentors included Ernst Cassirer, David Hilbert, Max Planck, Max Born, and Albert Einstein. Reichenbach earned his degree in philosophy at Erlangen in 1915 and published his dissertation on probability 1 year later. He nearly died during World War I on the Russian front but was able to attend Einstein's Berlin lectures in 1917–1920 on the theory of relativity. He gained a faculty position at Polytechnic (Stuttgart) in 1920 and in 1926 a chair in Berlin. He fled Germany when Hitler rose to power and taught at Istanbul until 1938, when he moved to the United States to finish his career at the University of California at Los Angeles.

Reichenbach's most important contributions in the philosophy and logic of natural language systems had to do with the problematic relation of meaning and truth. His most important contribution was the verifiability theory of meaning. In 1938, he published his thesis that the discovery of meanings to be associated with the conventional symbols of a language is dependent on the valid connection of those symbols with empirical facts. He disagreed with Bertrand Russell, who argued that meanings had to be discovered prior to the possibility of discovering any true representations. Reichenbach insisted that the discovery of meaning was dependent rather on prior discovery of certain truthful representations of known facts. Reichenbach agreed with Ludwig Wittgenstein's (1922) principle of testability as prerequisite to the meaningfulness of any sentence, and both disagreed with Russell. They insisted that truth is more basic than meaning. Reichenbach was greatly influenced by Einstein, who remarked that "everything depends on the degree to which words and word-combinations correspond to the world of impression" (1941/1956: 111).

Reichenbach (1947) provided the first serious effort by a logician other than C. S. Peirce to attempt a logical analysis of ordinary language. Throughout his life, he continued to explore Einstein's relativity as applied to conceptions of space, time, and the experience of empirical events. As a result, Reichenbach's writings inevitably probed the riddle put forth by Lev Vygotsky (1934/1962): What is the relation between language and thought? Reichenbach's best

Reinecke, John E. (1904–1982)

G T Childs, Portland State University, Portland, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

A pioneer in pidgin and creole studies, John E. Reinecke was relatively alone and isolated in promoting the study of Hawaiian Creole English (HCE) and other 'marginal languages.' In line with his involvement with the Hawaiian labor movement, Reinecke advocated the elevation of pidgins and creoles to the status of proper scientific object, just as he felt workers should be given their proper due. Reinecke's work on creole languages was interrupted by a long break of 20 years when he was banned from teaching because of his political activities.

Reinecke's politics came from a rather hardscrabble life beginning with a childhood as one of five children born to a tenant-farming family in Kansas. His education began in a one-room school house. The young boy soon began thinking of other places. He raced through whatever books were available and achieved acquired reading skills far beyond his years but could not go to high school in the next town because he was too young. His somewhat chaotic reading in his first years of college, coupled with his life experiences, led him to socialism, a political orientation later strengthened by his contacts with the exploited workers of Hawaii, whom he was soon to encounter as he indulged the urge to travel.

Reaching California early in 1926 and Hawaii by the end of the year, Reinecke found his new home. Although he traveled elsewhere, Hawaii was where his heart and scholarly interests lay. Reinecke's first period of productivity began with a survey of English on the island of Hawaii, resulting in his 1935 master's thesis, 'Language and dialect in Hawaii' (published in 1969). What was important about this first study was his adopting the perspective of the HCE speaker. Typically the view adopted was that of the Standard English speaker, the variety of the people in power, not the actual speakers of the variety.

In writing this thesis, Reinecke realized how little he (and the world) knew about such languages and conducted a remarkable survey as part of his dissertation. Sociologically oriented, his well known Ph.D. thesis appeared in 1937 as 'Marginal languages: a sociological survey of the creole languages and trade jargons,' a ground-breaking major work.

Reinecke's second period began with his being befriended by Stanley Tsuzaki, a specialist in contact languages at the University of Hawaii, who convinced Reinecke to re-enter the field. Together they produced *English in Hawaii: An Annotated Bibliography*, "the first scholarly bibliography of a creole" (Gilbert 1987: viii). Reinecke attended the first world conference on pidgin and creole languages (Mona, Jamaica, 1968) and soon became well known in the fledgling field. The two of them and others then produced *A Bibliography of Pidgin and Creole Languages* in 1975. From 1976 to 1982 Reinecke edited the first and only publication devoted to pidgin and creole studies at the time, *The Carrier Pidgin*, and in that publication continued to augment and update the 1975 bibliography that he and others had produced.

In 1975 Reinecke and his wife accepted an out-of-court settlement for the multiple civil rights' violations they had experienced, and thus received some compensation for their years of mistreatment. Up until the end of his life in 1982, Reinecke was involved with the Oral History Project at the University of Hawaii.

Reiner, Erica (b. 1926)

G Buccellati, University of California, Los Angeles, CA, USA

© 2006 Published by Elsevier Ltd.

As member of the editorial board and then editor-in-chief of the monumental *Chicago Assyrian Dictionary*, Erica Reiner emerged as a leading Assyriologist, with a thorough and profound knowledge of the textual-philological underpinnings of the discipline. This was further corroborated by her masterly editions of texts, ranging from religious (*Šurpu*) to astrological (*Inuma Anu Enlil*). But alongside these major achievements, she embraced a theoretical interest in the interpretation of the data that would have been considered iconoclastic were it not for the position of strength from which she was proposing it. The year 1966 was a landmark date in this respect: that is when her *A linguistic analysis of Akkadian* appeared in print.

Born in Hungary on August 4, 1926, Reiner studied first in Paris, where she earned a diploma in Assyriology from the Sorbonne (1951), and then moved to Chicago, where she completed her studies with a Ph.D. in Assyriology from the Oriental Institute of the University of Chicago (1955). She became an assistant professor there in 1956, John A. Wilson Professor in 1973, and John A. Wilson Distinguished Professor in 1983, the same year in which she also became editor-in-charge of the *Chicago Assyrian dictionary,* serving from 1973 to 1996, the longest tenure in this position during the project's eight decades.

She has recorded the long history of the dictionary project in her book *An adventure of great dimension* (2002). This is a remarkable account of events and personalities, written with the consummate skill of a historian and at the same time with the first-hand experience of a participant. Her insight and candor make for fascinating reading and allow a fresh new understanding of the forces that shaped one of the great lexicographical accomplishments of the 20th century. From the point of view of linguistics it is particularly significant because it highlights, in ways at times frankly dramatic, the confrontation between overarching theoretical concerns and the practical demands of logistic needs. She was a principal in both venues, as the most advanced theorist in the discipline and as the one responsible for the actual publication of the dictionary, nine volumes of which were prepared for publication under her tenure, out of 26 planned for the whole series. In fact, in a most interesting autobiographical self-disclosure, she relates how her linguistic vocation, so to speak, was rooted in a very early bitter disappointment resulting from a sharp criticism of the early stages of the dictionary, which contributed to her ever greater concentration on things 'grammatical' (2002: 72).

A linguistic analysis of Akkadian aimed at establishing a method of inquiry as much as at presenting a substantive body of data. It was a groundbreaking publication in 1966, and it remains so to this day. It accomplished two major goals. The first was to show how transformational grammar could be applied to a dead language, i.e., one whose carriers are no longer extant (there are no living speakers whose competence may be tapped). The second was to show Assyriologists how the application of general principles of analysis could bring greater clarity to what was otherwise perceived as a congeries of data whose coherence derived primarily from the philological accuracy of the underlying documentation. Its impact on the field has been limited, and that in the decades that followed its appearance there has been more lip service to its claims than a real confrontation with its substance. But this is mainly a reflection on the discipline, which is still largely rooted in a Neogrammarian mode. If anything, this proves even more abundantly how much ahead of her time Reiner was when the book appeared.

She revisited the subject in a brief but powerful general overview of Akkadian studies published four years later in *Current Trends in Linguistics* (1970), and dealt with a number of specialized topics in a series of articles that elucidated important concepts, especially with regard to phonemics and its relationship to the writing system. She also published an Elamite grammar (1969, written in 1960) that was groundbreaking in another sense, namely as the most thorough descriptive presentation of the language, which it remains to this day. This work exhibits an exemplary blend of philological accuracy and theoretical precision (even elegance), and serves as a textbook case of how strict adherence to method can help to elucidate raw data, especially in a case like Elamite,

As member of the editorial board and then editor-in-chief of the monumental *Chicago Assyrian Dictionary*, Erica Reiner emerged as a leading Assyriologist, with a thorough and profound knowledge of the textual-philological underpinnings of the discipline. This was further corroborated by her masterly editions of texts, ranging from religious (*Šurpu*) to astrological (*Inuma Anu Enlil*). But alongside these major achievements, she embraced a theoretical interest in the interpretation of the data that would have been considered iconoclastic were it not for the position of strength from which she was proposing it. The year 1966 was a landmark date in this respect: that is when her *A linguistic analysis of Akkadian* appeared in print.

Born in Hungary on August 4, 1926, Reiner studied first in Paris, where she earned a diploma in Assyriology from the Sorbonne (1951), and then moved to Chicago, where she completed her studies with a Ph.D. in Assyriology from the Oriental Institute of the University of Chicago (1955). She became an assistant professor there in 1956, John A. Wilson Professor in 1973, and John A. Wilson Distinguished Professor in 1983, the same year in which she also became editor-in-charge of the *Chicago Assyrian dictionary,* serving from 1973 to 1996, the longest tenure in this position during the project's eight decades.

She has recorded the long history of the dictionary project in her book *An adventure of great dimension* (2002). This is a remarkable account of events and personalities, written with the consummate skill of a historian and at the same time with the first-hand experience of a participant. Her insight and candor make for fascinating reading and allow a fresh new understanding of the forces that shaped one of the great lexicographical accomplishments of the 20th century. From the point of view of linguistics it is particularly significant because it highlights, in ways at times frankly dramatic, the confrontation between overarching theoretical concerns and the practical demands of logistic needs. She was a principal in both venues, as the most advanced theorist in the discipline and as the one responsible for the actual publication of the dictionary, nine volumes of which were prepared for publication under her tenure, out of 26 planned for the whole series. In fact, in a most interesting autobiographical self-disclosure, she relates how her linguistic vocation, so to speak, was rooted in a very early bitter disappointment resulting from a sharp criticism of the early stages of the dictionary, which contributed to her ever greater concentration on things 'grammatical' (2002: 72).

A linguistic analysis of Akkadian aimed at establishing a method of inquiry as much as at presenting a substantive body of data. It was a groundbreaking publication in 1966, and it remains so to this day. It accomplished two major goals. The first was to show how transformational grammar could be applied to a dead language, i.e., one whose carriers are no longer extant (there are no living speakers whose competence may be tapped). The second was to show Assyriologists how the application of general principles of analysis could bring greater clarity to what was otherwise perceived as a congeries of data whose coherence derived primarily from the philological accuracy of the underlying documentation. Its impact on the field has been limited, and that in the decades that followed its appearance there has been more lip service to its claims than a real confrontation with its substance. But this is mainly a reflection on the discipline, which is still largely rooted in a Neogrammarian mode. If anything, this proves even more abundantly how much ahead of her time Reiner was when the book appeared.

She revisited the subject in a brief but powerful general overview of Akkadian studies published four years later in *Current Trends in Linguistics* (1970), and dealt with a number of specialized topics in a series of articles that elucidated important concepts, especially with regard to phonemics and its relationship to the writing system. She also published an Elamite grammar (1969, written in 1960) that was groundbreaking in another sense, namely as the most thorough descriptive presentation of the language, which it remains to this day. This work exhibits an exemplary blend of philological accuracy and theoretical precision (even elegance), and serves as a textbook case of how strict adherence to method can help to elucidate raw data, especially in a case like Elamite,

where these data are very scanty – for instance, in her treatment of syntax, where even the definition of sentence boundary is problematic (1969: 93).

Reiner's other major contribution has been toward a proper interpretive understanding of Akkadian literature, particularly with regard to a formal criteria of analysis. In this area, she has provided not a theoretical synthesis, but rather a how-to demonstration that applies carefully defined principles to specific individual texts. Her 1978 'Die akkadische Literatur' contains insightful, if brief, pointers at problems to be solved and pathways that may be followed, though it does otherwise primarily deal with plot and character in the texts analyzed according to their genre, which leads to occasional interesting comments on the notion itself and on pertinent classification criteria. Only in the case of the so-called Wisdom Literature does Reiner provide a more detailed formal analysis of specific stylistic mechanisms, in particular with regard to the structure of the stanza of a given text.

The same approach is more fully developed in her 1985 work *Your thwarts in pieces*, an anthology that embodies a system. Through a highly polished critical analysis of a number of texts, Reiner defines a series of formal mechanisms that almost add up to a systematic *ars poetica Mesopotamica*, something which, she rightly stresses, was never formulated by the Mesopotamians themselves and thus can only be attained through a rigorous articulation of demonstrable recurrent patterns. This she does in a masterly way for texts in prose and poetry, so that this slender volume may well be considered the best presentation yet of Mesopotamian literature *qua* literature (rather than as textual philology). With great subtlety, she identifies a whole series of devices, such as fronting, inversion, and marking in word order (sometimes supported by graphic devices on the tablets); foregrounding in a poem's literary structure (i.e., the identification of thematic pivots around which the structure revolves); the economy of the salient points that undergird the plot and more sharply define the characters (with diachronic comparisons where possible) and, conversely, of plain filler motifs; explicit markers that signal a subdivision into discrete units formally identifiable as sections, stanzas, distichs, 'antiphonic groups,' or the like; the patterned recurrence of unexpected grammatical sequences; spelling patterns that may contribute to define a metrical scheme; the impact of metaphors; compositional devices such as parallelism and concatenation; sound patterns that bracket noncontiguous segments. Thus it is that her linguistic sophistication serves her in good stead in her effort to understand the deeper levels of meaning, i.e., to achieve and share a controlled "literary competence." It is remarkable how the formal analysis she proposes and practices contributes to nurturing that "loving immersion" in a text, that "poetic feeling" about which she speaks elsewhere as a parallel to the "linguistic feeling" that one can develop even vis-à-vis a dead language and its literature.

Reinhart, Tanya

C Parodi, University of California, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Tanya Reinhart is a professor at Tel Aviv University in Israel and the University of Utrecht in the Netherlands. She is a prominent figure in formal syntax and semantics, discourse analysis, and linguistics and literature.

She received her B.A. in philosophy and Hebrew literature (1964–1967) at the Hebrew University in Jerusalem, her M.A. in comparative literature and philosophy (1967–1969) from the same university, and her Ph.D. in linguistics from the Massachusetts Institute of Technology (1972–1976). Her dissertation, *The syntactic domain of anaphora*, supervised by Noam Chomsky, is a major contribution to the fields of syntax and semantics. In this work, she defines syntactic domains of coreference and c-command, which were the basis for all generative studies on coreference in the framework of the Extended Standard Theory during the 1970s and the 1980s.

In her 1983 book *Anaphora and semantic interpretation*, within the Chomskian framework of the autonomy of syntax and interpretative semantics, she argues that anaphora restrictions obey general syntactic conditions on all interpretative rules, including sentence-level linguistic rules. She claims that these syntactic conditions reflect properties of the processing ability of the mind. She departs from her dissertation in that she abandons noncoreference or disjoint-reference rules in favor of the semantics of anaphora because this distinction is needed to distinguish between pragmatic coreference and bound anaphora, since only the latter is restricted by sentence-level rules. Later on, in her 2000 paper, 'Strategies of anaphora resolution,' she claims the traditional distinction between binding and coreference should be modified to differentiate between binding and covaluation. While α Argument-binds β iff α is the sister of a λ-predicate whose operator binds β, covaluation is an interface strategy. Covaluation is a relation between two elements that are not bound, but have the same value (α and β are covalued iff neither Argument-binds the other and they are assigned the same value). Covaluation is available regardless of the referential status of the antecedent, and shows up also in quantified contexts. Covaluation is independent from the computational system.

Lately Professor Reinhart has been analyzing the syntax and semantics of the thematic system of verbs. She has also researched the acquisition of syntax in children. In her 1999 study on the acquisition of stress shift and focus in children, she found that computing the focus obtained by stress shift requires constructing a comparison set in a similar fashion as coreference in children. In the case of stress shift, there is no evidence that children have general problems acquiring it, but there is a 50% range of performance when stress shift applies. This was predicted by the processing cost hypothesis in tests on coreference, which predicts a 50% performance in children between the ages of 3.8 and 4.6.

Reinisch, Simon Leo (1832–1919)

S Pugach, Ohio State University, Lima, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Simon Leo Reinisch (known as Leo) was born in Osterwitz, Austria, on October 26, 1832, and died on December 24, 1919, in Lankowitz, Austria. He was the fifth of nine children born to Josef R. Reinisch and Elisabeth Spieler, who were Styrian peasants. In 1846 Reinisch began *Gymnasium* in Graz, and he enrolled at the University of Vienna in 1854. While in Vienna, he studied the history of the ancient Middle East, with an emphasis on Egypt, and learned to read hieroglyphics. After completing his studies in 1857, Reinisch worked briefly as a scribe – an amanuensis – at Vienna's university library. He received a doctoral degree from the University of Tübingen in 1859, and completed postdoctoral studies back in Vienna in 1861 with a thesis entitled 'The history of the Orient in ancient times with reference to Egypt.' In 1865–1866 the emperor Maximilian sent Reinisch to Egypt for the first time. Reinisch's stay in Egypt proved fruitful, as he collaborated on translating inscriptions with historian Robert Rösler and Egyptologist Richard Lepsius (*see* **Lepsius, Carl Richard (1810–1884)**). At Maximilian's request, Reinisch also catalogued all of the artifacts he saw in Miramar. During Reinisch's expedition to Egypt, his benefactor Maximilian, who had been emperor of Mexico since 1864, called upon Reinisch to become director of Mexico's main archaeological museum. Once in Mexico, in the short period before Maximilian's execution in 1867, Reinisch made a thorough study of the region's languages and prehistory. Reinisch also collected copious textual and archaeological material for Maximilian in both Egypt and Mexico, since the emperor hoped to display a wide range of ethnographic objects in Austrian and Mexican museums (Anders, 1987).

Habsburg emperor Franz Josef named Reinisch Professor of Egyptology at the University of Vienna in 1868; he was then promoted in 1873. The older he grew, the more Reinisch dedicated himself to linguistics instead of history, teaching the former much more frequently than the latter. Still, even when he was a young university student in Vienna, Reinisch had always insisted that philology was crucial for the study of history, and for him it remained so. Reinisch was also a comparativist, interested in how the far-flung languages he had learned were interrelated. For this reason, Reinisch believed that grammar should rest at the center of any comparative philological studies, because its structure was the surest key to divining relationships among languages. Reinisch considered the so-called 'Hamitic' languages to have the same structure as the Semitic and Egyptian ones, and held that they could furthermore be linked to the Indogermanic language family; moreover, he maintained that all of these were likely related to Bantu and Nigritic languages (Duchâteau, 1987; Böhm, 1987; Reinisch, 1873). Reinisch was also concerned with the cultural aspects of language research, and was careful about correlating linguistic and ethnographic phenomena (Anders, 1987). An expert in North African languages, Reinisch traveled to the Sudan and Eritrea in the 1870s and 1880s to research Cushitic languages, and he is counted today as the founder of Cushitic studies. Unlike many pre–World War I Africanist linguists, Reinisch, who was a religious Christian, was not a missionary, but he did translate the Gospels into Bilin (Bilen) and Qara (Jibbali). Even though Reinisch became Rector and then Dean of the University of Vienna in the 1890s, he continued to be actively involved in linguistics, and was one of three editors of the *Wiener Zeitschrift für die Kunde des Morgenlandes*. He also published Adolf Schleicher's Somalian texts after Schleicher's death, when they otherwise would have remained hidden (Schleicher, 1900; Jungraithmayr and Möhlig, 1983). Reinisch retired from academia in 1902, when he was also given emeritus status and received a medal from his university colleagues honoring his lifelong scholarly achievements (Duchâteau, 1987).

Reisig, Karl (1792–1829)

P C Sutcliffe, Colgate University, Hamilton, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Christian Karl Reisig, born November 17, 1792 in Thuringia, was an outstanding professor of classical philology who taught in Jena (1817–1820) and Halle (1820–1828) before his early death on a study trip to Venice on January 17, 1829. He studied under Gottfried Hermann in Leipzig (1809–12) and Christian Heyne in Göttingen (1812–13), completing his doctorate in 1817 after a three-year stint in the Saxon army. He published several works on Aristophanes's comedies, but is primarily remembered today for his *Vorlesungen über lateinische Sprachwissenschaft* (1839), which were compiled and edited from his hieroglyphic lecture notes by his student Friedrich Haase.

Reisig's *Vorlesungen* are divided into three volumes, *Etymologie, Lateinische Semasiologie oder Bedeutungslehre*, and *Lateinische Syntax*, of which only the second is traditionally considered, when Reisig is remembered at all, in determining his historical significance. He is most often remembered in the context of semantic history (e.g., Gordon) as the inventor of the word 'semasiology' and for having introduced semantics as an independent discipline, a third component of grammar next to etymology and syntax. Based solely on Reisig's second volume, his investigation of meaning is typically construed as being limited to historical semantic shifts, a reading that was influenced by Reisig's successors/editors, Haase and Heerdegen (Schmitter, 1985: 646; Nerlich, 2001: 1598).

However, Schmitter (1985) reviews all three volumes to reveal a much broader, more complete conception of meaning in Reisig's work, incorporating both diachrony and synchrony. Diachronically, Reisig emphasizes the need to determine not only successive meanings of the same word, but also the logical relationship between these meanings that motivated the changes. Reisig discusses idea assocations typical of semantic shift, including metaphor, metonymy, and synecdoche, raising them to the status of logico-rhetorical laws of semantic change (Nerlich, 2001: 1597). Synchronically, the logical relationship between connected, 'synonymous' concepts must be determined in order to establish the precise meanings of words (Reisig's 'synonymologie'). Thus, word meaning consists not only of a 'concept' but also of age, style, register, and so forth. The 72-page introduction to Volume I contains Reisig's 13 principles of language and its study, including general linguistic rules based on Kant's categories of understanding (*see* **Kant, Immanuel (1724–1804)**) (Schmitter, 1985: 652).

Reisig's immediate successors, especially Haase and Heerdegen, criticized his overly broad conception of meaning as having little to do with semasiology, which, they believed, should be limited to the denotative meanings of individual words. Other followers included Albert Agathon Benary, Oskar Hey, and Max Hecht. In the theory of semantic fields today, and in Coseriu's (*see* **Coseriu, Eugenio (1921–2002)**) theory of lexical solidarities, we see the reemergence of ideas that were central to Reisig's conception of meaning (Schmitter, 1985: 660).

Reiske, Johann Jacob (1716–1774)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Johann Jacob Reiske was born on December 25, 1716 in Zörbig, Germany. After spending four years at the *Waisenhaus* (orphanage) in Halle undergoing a somewhat unprofitable high school education, he entered the University of Leipzig in 1734, at the age of 17. Formally enrolled to study theology, he did not attend any classes, devoting his time instead to learning Greek, Hebrew, and Arabic on his own. After five years, he left Leipzig for Leiden, hoping to increase his knowledge of Arabic with the help of manuscripts available only in Leiden and Amsterdam. While he was forced to work many hours for his livelihood – mostly by copying manuscripts and offering private lessons – he took courses in Arabic with Albert Schultens (1686–1750) and in Greek with Tiberius Hemsterhuis (1685–1766). After four years in Leiden, he began, at the advice of Schultens, to study medicine and obtained a doctor's degree in 1746 without ever practicing medicine. He returned to Leipzig that year. Again he had to make his living by taking on odd jobs only marginally related to his interests and exceptional capabilities. His appointment to a professorship in Arabic in 1748 brought no relief, because the remuneration was less than adequate and ceased to be paid after some years. Even upon his election to principal of the Nicolai School in 1858, his economic situation did not substantially improve, because the administrative work severely curtailed the available time to do what he liked best – preparing materials in Oriental and classical languages for publication (see Bibliography).

In spite of overwhelming adversities, his enormous productivity never abated. In Arabic studies, he created an innovative approach – that earned him the distinction of being called 'recht eigentlich der Begründer der arabischen Philologie' (Foerster, 1889: 131) – in that his major interest in Arabic was not motivated primarily by linguistic or theological concerns, but by his desire to evaluate Arabic as a language and culture in its own right. His extraordinary status, having mastered two scientific areas, the Arabic and the Greek, and being 'der erste Arabist und einer der ersten, wenn nicht der erste Gräcist des 18. Jahrhunderts' (Foerster, 1889: 131), is acknowledged by numerous distinguished personalities, including Herder, Theodor Mommsen, Heinrich L. Fleischer, and Lessing.

The greater part of Reiske's misfortune was caused by his difficult personality. He often managed to offend those people who wanted to be supportive. His marriage to Ernestine Christine Müller (1735–1798) in 1764, on the other hand, proved to be the most beneficial occurrence of his entire life. He had taught her to become a competent classical scholar in her own right, but all through her married life she selflessly contributed to the advancement of his projects and helped him realize his full potential. After his death (August 14, 1740), she completed and published many of his manuscripts that had been left unfinished. Meusal (1811) provides the most complete Reiske bibliography.

Reiske, Johann Jacob (1716–1774)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Johann Jacob Reiske was born on December 25, 1716 in Zörbig, Germany. After spending four years at the *Waisenhaus* (orphanage) in Halle undergoing a somewhat unprofitable high school education, he entered the University of Leipzig in 1734, at the age of 17. Formally enrolled to study theology, he did not attend any classes, devoting his time instead to learning Greek, Hebrew, and Arabic on his own. After five years, he left Leipzig for Leiden, hoping to increase his knowledge of Arabic with the help of manuscripts available only in Leiden and Amsterdam. While he was forced to work many hours for his livelihood – mostly by copying manuscripts and offering private lessons – he took courses in Arabic with Albert Schultens (1686–1750) and in Greek with Tiberius Hemsterhuis (1685–1766). After four years in Leiden, he began, at the advice of Schultens, to study medicine and obtained a doctor's degree in 1746 without ever practicing medicine. He returned to Leipzig that year. Again he had to make his living by taking on odd jobs only marginally related to his interests and exceptional capabilities. His appointment to a professorship in Arabic in 1748 brought no relief, because the remuneration was less than adequate and ceased to be paid after some years. Even upon his election to principal of the Nicolai School in 1858, his economic situation did not substantially improve, because the administrative work severely curtailed the available time to do what he liked best – preparing materials in Oriental and classical languages for publication (see Bibliography).

In spite of overwhelming adversities, his enormous productivity never abated. In Arabic studies, he created an innovative approach – that earned him the distinction of being called 'recht eigentlich der Begründer der arabischen Philologie' (Foerster, 1889: 131) – in that his major interest in Arabic was not motivated primarily by linguistic or theological concerns, but by his desire to evaluate Arabic as a language and culture in its own right. His extraordinary status, having mastered two scientific areas, the Arabic and the Greek, and being 'der erste Arabist und einer der ersten, wenn nicht der erste Gräcist des 18. Jahrhunderts' (Foerster, 1889: 131), is acknowledged by numerous distinguished personalities, including Herder, Theodor Mommsen, Heinrich L. Fleischer, and Lessing.

The greater part of Reiske's misfortune was caused by his difficult personality. He often managed to offend those people who wanted to be supportive. His marriage to Ernestine Christine Müller (1735–1798) in 1764, on the other hand, proved to be the most beneficial occurrence of his entire life. He had taught her to become a competent classical scholar in her own right, but all through her married life she selflessly contributed to the advancement of his projects and helped him realize his full potential. After his death (August 14, 1740), she completed and published many of his manuscripts that had been left unfinished. Meusal (1811) provides the most complete Reiske bibliography.

Relational Network Grammar

D C Bennett, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Relational network grammar (RNG) is a more general label for the linguistic theory that used to be known as stratificational grammar (SG). The latter originated in the late 1950s when Sydney Lamb combined a version of Bloomfieldian structuralism with ideas from Hjelmslev's Glossematics. RNG now operates with a much looser conception of stratification and has also undergone a considerable broadening of its goals. Even SG itself was never content to concentrate on 'competence' to the exclusion of 'performance,' preferring instead to provide an account of language that can be used to model the processes of speech production and comprehension. However, besides this feature of the theory, referred to now (Lamb, 1999: 293) as the requirement of 'operational plausibility,' two further requirements have been added: those of 'developmental plausibility' and 'neurological plausibility' (1999: 293) – i.e., that a realistic theory should (a) provide a plausible account of how the proposed linguistic system can be learned, and (b) be compatible with what is known about the brain from neurology and cognitive neuroscience. The remainder of this article is divided into four sections. The first section presents details of SG; the second discusses language as a network of relationships; the third mentions the relationship between complex lexemes, constructions, and syntax; and the fourth expands on operational, developmental, and neurological plausibility.

Stratificational Grammar

Tactics vs. Realization

The Bloomfieldian model of language of Hockett (1955: 14) contained three central subsystems: phonology, grammar, and morphophonemics. The phonology and grammar crucially incorporated a mechanism for specifying possible combinations of phonemes and morphemes respectively. In the case of phonology this was referred to as the 'phonotactics,' and the '-tactics' part of this term formed the basis of such later coinings as 'morphotactics,' 'lexotactics' and 'semotactics.' Hockett's (1955) 'grammar' subsystem was in effect a morphotactics. The morphophonemic subsystem, on the other hand, had a different function, in that it characterized the representation – or 'realization' – of morphemes in terms of phonemes, and therefore formed a bridge between grammar and phonology. Hockett's (1955) model was equivalent to a two-stratum SG.

One of the two main features that SG derived from Glossematics was its concern with 'content' as well as 'expression' (Hjelmslev, 1961: 47–60, 66–67, 70–72). This entailed an immediate increase in the number of strata recognized. (For the other main feature from Glossematics, see 'A Network of Relations' below.) During the 1960s, 1970s, and 1980s, the number of strata posited was under continuous review, but the four-stratum model of **Figure 1** was commonest (Gleason, 1964; Lamb, 1964, 1971). Evidence in support of stratal distinctions was of two kinds, tactic and realizational. Tactic evidence will be discussed in 'Independent Patterning' below. Realizational evidence consisted in identifying examples of the same

Relational Grammar and Arc-Pair Grammar

Overview

Relational Grammar (RG) is a generative framework developed in the 1970s and 1980s. The framework was first developed by David Perlmutter and Paul Postal and presented to the linguistic community in a seminar at the 1974 LSA Summer Institute in Amherst, Massachusetts. As the name indicates, Relational Grammar gives theoretical primacy to GRAMMATICAL RELATIONS (GRs), such as SUBJECT, DIRECT OBJECT, etc. Transformational Grammar defined tree-theoretic primitives and derived GRs in terms of tree relations – e.g., SUBJECT was defined as 'NP daughter of S'. The premise of RG was that a good deal of grammatical phenomena is better analyzed directly in terms of GRs, without the intermediate step of tying the GRs to constituency.

RG was one of several generative frameworks that emerged as alternatives to Standard Transformational Grammar in the late 1970s and early 1980s. As such, it participated in a fertile literature that explored the roles of theoretical constructs such as GRAMMATICAL RELATIONS, CONSTITUENT STRUCTURE, and MONO-versus MULTI-STRATAL representations (for example, see several contributions in Jacobson and Pullum, 1982). As noted above, RG granted a primitive status to GRs; in addition, like Transformational Grammar, it was MULTI-STRATAL; that is, it defined a clause structure in a series of strata that expressed the relational structure of the clause at different points of analysis. Hence, RG defined INITIAL, INTERMEDIATE, and FINAL strata in a manner that was similar to Transformational Grammar's DEEP, INTERMEDIATE, and SURFACE structures. Unlike the DERIVATIONAL Transformational Grammar, however, RG developed into a REPRESENTATIONAL framework. Other frameworks of this period include EXTENDED STANDARD THEORY/GOVERNMENT AND BINDING THEORY (GB – constituent-based, multi-stratal), GENERALIZED PHRASE STRUCTURE GRAMMAR (GPSG – constituent-based, mono-stratal), and LEXICAL-FUNCTIONAL GRAMMAR (LFG – both constituent- and relationally based, mono-stratal, multi-level).

Research in RG is characterized by close attention to empirical detail from a wide variety of languages. The goal of much of this work was to establish an inventory of relational structures in natural language and tease apart universal aspects (LAWS) from language-particular instantiations (RULES). Some of this work marshaled RG analyses of natural language data to argue in favor of the use of GRs as primitives (e.g., Perlmutter and Postal, 1983c), as well as the multi-stratal characteristic of the framework (e.g., Perlmutter, 1982).

Arc-Pair Grammar (APG) (Johnson and Postal, 1979) seeks to formalize the laws and rules of RG more rigorously. In addition, it posits the theoretical devices of SPONSOR and ERASE (see below) – these allow for a more precise characterization of relational structures, and increases the empirical coverage of the framework.

While there was considerable RG research activity in the 1980s, work in this framework had essentially ended. Nevertheless, significant empirical, analytical, and theoretical generalizations uncovered in RG work have had a profound influence on the nature of linguistic research from a wide array of theoretical perspectives.

Relational structures are defined in RG through RELATIONAL NETWORKS (RNs). An RN is a set of ARCS, each of which defines a relationship between linguistic elements. For example, the English sentence in (1) might have the RN in (2):

(1) The agent bought the house.

(2)

The RN in (2) consists of three arcs; each indicating a relationship between a clausal element 'a' with a phrase. For example, one arc shows that the phrase *the agent* bears the subject relation ('1') to clause 'a'; another indicates that *bought* bears the predicate relation ('P'), and the third represents *the house* as bearing the direct object relation ('2'). Thus, the definition of an arc must include its tail (in these cases the clause 'a'), its head (*the agent*, *bought*, or *the house*), and a grammatical relation. RG defines a finite set of

universal grammatical relations, represented by their corresponding RELATIONAL SIGNS (R-SIGNS), some of which are given in (3):

(3) Some Grammatical Relations (GRs)

GR	*R-sign*
subject of	1
direct object of	2
indirect object of	3
benefactive of	Ben
instrumental of	Instr
locative of	Loc
chômeur of	Chô

Arcs that bear the 1 R-sign are referred to as 1-arcs; those that bear the 2 R-sign are called 2-arcs, etc.

In addition to the tail, head, and grammatical relation, the arcs in (2) also specify a COORDINATE (in each case, 'c_1'). This indicates at which strata the head bears the specified relation to the tail. Because the RN in (2) shows only one stratum, the coordinates are the same for all three arcs. The RN in (5), which corresponds to the passive example in (4), shows a less trivial use of coordinates:

(4) The house was bought by the agent.

(5)

The RN in (5) shows five arcs. Again, the tail of each arc is the clausal node 'b'. However, in (5) *the house* heads two distinct arcs – a 2-arc and a 1-arc. Notice that these arcs have distinct coordinates – c_1 and c_2, respectively. This represents the claim that *the house* is a direct object at the first (INITIAL) stratum, but a subject at the second (and in this case, FINAL) stratum. This aspect of the RG analysis of passive recalls the Standard Theory treatment where the Surface Structure subject of a passive clause corresponds to a Deep Structure object. An alternative representation of the relational network in (5) is given in (6). This STRATAL DIAGRAM brings the strata into focus. Note that in a stratal diagram, the arrow headed by *the house* actually represents two distinct arcs (the two arcs headed by *the house* in 5).

(6)

The mechanism by which *the house* heads two distinct arcs is that of REVALUATION (in this case ADVANCEMENT). Revaluations are sanctioned by rules, such as the PASSIVE rule in (7):

(7) Passive is the rule . . . that sanctions the existence of a 1-arc for a nominal N_a in stratum c_{k+1} of a clause node C, where N_a heads a 2-arc in stratum c_k of C, and where there is some nominal, N_b, which bears a 1-arc in stratum c_k. (Perlmutter and Postal, 1983c: 18)

The rule in (7) is part of a universal inventory of relation-changing operations. Languages may include a subset of these rules. Thus, while the choice of a passive operation is language-specific, the characterization of Passive (and other relation-changing phenomena) is part of a universal set of possible relation changes. This aspect of RG foreshadows aspects of both Construction Grammar (language-particular grammars choose certain constructions) and Optimality Theory (there is a universal inventory of grammatical principles – in this case, relation-changing operations).

The rule in (7) requires that the clause contain a 1-arc at the same stratum as the 2-arc that advances. Note that in (5) there are two arcs headed by *by the agent*. At stratum, c_1, *by the agent* heads a 1-arc. At stratum c_2, it heads a Cho-arc. The CHÔMEUR relation (named for the French term for 'unemployed') is borne by elements whose GR has been taken over by another element.

RG posits two universal laws that contribute to the final-stratum chômeur status of the *by the agent*: the STRATAL UNIQUENESS LAW and the CHÔMEUR LAW. The former, formulated in (8), guarantees that no stratum will have more than one 1-arc, 2-arc, or 3-arc (these R-signs label the TERM RELATIONS – i.e., 'subject of,' 'direct object of,' and 'indirect object of').

(8) Stratal Uniqueness Law
Let 'term' be a variable over the class of term R-signs, that is, '1', '2', and '3'.
Then: If arcs A and B are both members of the c_k stratum (*b*) and A and B are both $term_x$ arcs, then A = B. (Perlmutter and Postal, 1983b: 92)

The Stratal Uniqueness Law guarantees that when *the house* advances to subject, *the agent* must assume some other GR. The fact that this other GR is chômeur is dictated by the Chômeur Law:

(9) Chômeur Law
If an RN contains arcs of the form $[Term_x(a,b)/\langle_{cu}c_k c_y\rangle]$ and $[Term_x(c,b)\langle_{ck+1}c_z\rangle]$, then it contains an arc of the form $[Cho(a,b)\ \langle_{ck+1}c_w\rangle]$. (Perlmutter and Postal, 1983b: 96)

The Chômeur Law ensures that when an arc assumes a GR already borne by another arc (OVERRENS, in APG terminology), the latter arc must assume the chômeur GR. Thus, when the initial 2-arc in (5) advances to become a 1-arc, the original 1-arc must assume the chômeur relation.

An additional RG Law limits the chômeur relation to situations where an arc is overrun:

(10) Motivated Chômage Law
An RN containing an arc of the form $[Cho(a,b)\langle_{ci}c_w\rangle]$ also contains distinct arcs of the form $[Term_x(a,b)\langle_{cu}c_{i-1}\rangle]$ and $[Term_x(c,b)\langle_{ci}c_z\rangle]$. (Perlmutter and Postal, 1983b: 99)

Together these laws constrain the class of legal RNs where relation changes create new term arcs. If the new term arc comes in conflict with an existing term arc, the latter must assume the chômeur relation; this is the only way a Cho-arc can come about.

Major Contributions of RG

Research in the RG framework has influence in both its cross-construction and cross-linguistic emphasis. The following sections will briefly survey five construction types where RG has made important contributions.

Passive

Perlmutter and Postal's 1977 *BLS* paper "Toward a Universal Characterization of Passivization" (revised and republished as Perlmutter and Postal, 1983c) showed the cross-linguistic value in conceiving of cyclic phenomena in terms of grammatical relations rather than in terms of constituent structure-changing transformations. The transformational approach, as assumed under Standard Theory, moves an NP from a VP-internal position to become the NP daughter of S. In addition, it must specify a morphological change on the verb and somehow demote the original NP daughter of S – e.g., to a post-verbal PP in English. The problem with this approach is that it requires a wide variation in the formulation of passive from language to language. While in English, the basic SVO word order requires leftward movement of the VP-internal NP and rightward movement of the original NP daughter of S, other languages will require different movements. These differences must be hardwired into the transformations themselves. Furthermore, many of these differences are predictable from the basic word order facts of the languages. The following examples illustrate some of these cross-linguistic differences:

(11) *English – SVO*
a. Louise reviewed that book. (active)
b. That book was reviewed by Louise. (passive)
(Perlmutter and Postal, 1983c: 3)

(12) *Turkish–SOV*
a. Hasan bavulu açtı. (active)
Hasan suitcase-ACC open-PST
'Hasan opened the suitcase.'
b. Bavulu (Hasan tarafindan) açıldı. (passive)
suitcase (Hasan by) open-PASS-PST
'The suitcase was opened by Hasan.'
(Perlmutter and Postal, 1983c: 4–5)

Notice that in addition to word order differences, these examples illustrate morphological differences in passives (copula + participle in English vs. verbal suffix in Turkish), as well as different strategies for marking the nominal that corresponds to the active subject (preposition in English vs. postposition in Turkish).

Perlmutter and Postal point out that, cross linguistically, passive constructions have two crucial characteristics:

(13) a. A direct object of an active clause is the (superficial) subject of the 'corresponding' passive.
b. The subject of an active clause is neither the (superficial) subject nor the (superficial) direct object of the 'corresponding' passive. (Perlmutter and Postal, 1983c: 9)

The RG analysis sketched above captures these generalizations directly; a 2-arc advances, yielding a 1-arc; this new 1-arc overruns the original 1-arc, putting it *en chômage*. The cross-linguistic differences in passives follow from general language-particular word order facts and different morphologies.

While modern syntactic frameworks adopted analyses of passive that avoided the missed generalizations

of the Standard Theory account, the RG analysis was among the first to do so.

Unaccusatives

The UNACCUSATIVE HYPOTHESIS is probably the best-known contribution of RG research. In the mid–1970s, David Perlmutter and Paul Postal began discussing the possibility that intransitive clauses bifurcate into those where the superficial subject is also an underlying subject (UNERGATIVES) and those where it is an underlying object (UNACCUSATIVES). While there was some precedent for this style of analysis in transformational and earlier literature, theirs was the first explicit formulation of this account for purely intransitive predicates. The RG analysis of this contrast is illustrated in (14):

(14)

Notice that the 2 to 1 advancement in (14b) creates a final 1-arc. Had this advancement not occurred, the clause would lack a final subject. RG posits the following law to prohibit clauses that lack final subjects:

(15) Final-1 Law
If there is a c_k stratum of *b* and no c_{k+1} stratum of *b*, we say that the c_k stratum is the 'final' stratum of *b*.
Then: if *b* is a basic clausal node, the final stratum of *b* contains a 1-arc. (Perlmutter and Postal, 1983b:100)

Unaccusative Advancement is, then, one way to rescue an RN from violating the Final-1 Law.

The best-known evidence for the unergative/unaccusative contrast comes from Dutch impersonal passives and a cluster of phenomena in Italian. The former evidence was presented in Perlmutter (1978); in this work he proposes the following universal law:

(16) The 1-Advancement Exclusiveness Law
In a relational network in which A and B are neighboring 1-arcs (i.e., 1-arcs with the same tail), if A is an advancee arc, B is *not* an advancee arc. (Perlmutter, 1978: 166)

The effect of this law is to disallow more than one advancement to subject in a given clause. Since unaccusatives involve 2–1 advancement and so do passives, the prediction is that passives should be disallowed with unaccusative predicates. Setting aside certain complications stemming from the difference between PERSONAL and IMPERSONAL passives, this prediction is borne out in the following contrast from Dutch:

(17) a. Er wordt door hem altijd gedubd. *unergative – passive ok*
'It it is always thought deeply be him.'
b. *Er werd door de kinderen in Amsterdam gebleven. *unaccusative – passive* *
'It was remained by the children in Amsterdam.' (Perlmutter, 1978: 168–169)

The evidence for unaccusativity in Italian was presented in talks by Perlmutter in the late 1970s. Some of these arguments were published in Perlmutter (1983a), but a full treatment of the phenomena was not published until Perlmutter (1989). In the meantime, these ideas were developed in two 1981 dissertations (published as Rosen, 1988; and Burzio, 1986, respectively); in Burzio's work, the RG analysis was translated into a configurational Government and Binding framework.

The best-known Italian phenomena tied to the unergative/unaccusative contrast comes from the fact that perfect constructions with intransitive predicates bifurcate into those that use the auxiliary *avere* 'have' and those that use *essere* 'be':

(18) a. Giorgio *ha (*è)* lavorato. *unergative*
'Giorgio worked.'
b. Giorgio *è (*ha)* sparito. *unaccusative*
'Giorgio disappeared.' (Perlmutter, 1989: 64)

The bifurcation of intransitives in terms of auxiliary selection correlates closely with a number of other properties, including the possibility of certain participial constructions and partitive *ne*-cliticization.

The Unaccusative Hypothesis has been influential in theoretical syntax. Unaccusative constructions have been explored in a wide variety of languages and have joined constructions such as Passive and Raising as standard aspects of syntax. Nevertheless, there have been attempts to derive some of the effects associated with unaccusativity from lexical semantic and aspectual factors (e.g., Bresnan and Zaenen, 1990; and Levin and Rappaport Hovav, 1995). Regardless of the ultimate fate of the Unaccusative Hypothesis, the clusters of phenomena associated with it have been the subject of intense research since its conception.

Inversions

Just as the Unaccusative Hypothesis distinguishes final 1s on the basis of their initial stratum GR, the INVERSION analysis bifurcates the class of final 3s. These phenomena were originally discussed in Harris'

1976 dissertation (see also Harris, 1984). She adopted the term INVERSION from the traditional grammatical literature on Georgian. In Georgian, a class of predicates can have superficial datives that, nevertheless, exhibit behaviors associated with subjects. For example, they are able to antecede subject-oriented reflexives, as in (19):

(19) Galas turme daurçmunbia
Gela-NOM apparently he-convinced-him-EV
tavisi tavi.
self's self-NOM
'Apparently Gela (has) convinced himself.'
(Harris, 1984: 267)

In addition, these datives (INVERSION NOMINALS) can trigger number agreement – another property generally limited to subjects.

Under the inversion analysis, an inversion nominal heads an initial 1-arc, and demotes to become a 3-arc. To satisfy the Final-1 Law, a new 1-arc must be introduced – if the clause has a 2-arc at the stratum preceding inversion, it might advance (and the clause will be unaccusative):

(20)

Inversion constructions have been proposed for a wide variety of languages – often associated with psychological predicates. For example, Perlmutter (1984) argues that a class of predicates in Italian determines initial 1-arcs that advance to 3. He argues for the notion WORKING-1; i.e., an element that heads a 1-arc at some stratum and a final term-arc (i.e., a 1-, 2-, or 3-arc). In this way, subject behaviors, such as the ability to antecede reflexives and control into adjunct clauses, can be associated with a natural class – the class of nominals that are subjects at some stratum but not put *en chômage*. Notice that this type of analysis crucially relies on the multi-stratal character of the framework.

There have been two challenges to the inversion analysis. One, presented in Anderson (1984), reanalyzes the Georgian inversion nominals as dative-marked subjects. That is, he challenges the final 3-hood of these elements. Anderson speculates that other putative inversion constructions might be subject to a similar analysis. Indeed, such dative-subject analyses have been common for a number of languages (e.g., Belletti and Rizzi's 1988 account of Italian psychological predicates (Belleti and Rizzi, 1988)). Moore and Perlmutter (2000) address this issue in the context of Russian. In Russian there are two distinct constructions that might be analyzed as having dative subjects: infinitival clauses with overt (dative) arguments and constructions that were previously analyzed as inversion constructions. Moore and Perlmutter argue that the former are true dative subject constructions, but the latter are not; the two constructions contrast in several key ways.

The other challenge to the inversion account maintains the superficial object status of the inversion nominal, but dispenses with its initial subjecthood. This is common in LFG accounts, because of the mono-stratal character of the framework. The subject behaviors of the inversion nominal are tied to another level of representation. For example, Alsina (1996) attributes such properties of certain Catalan nominals to the elements' high position at ARGUMENT STRUCTURE – a level that is based on semantic roles.

Again, the RG inversion analysis provided a productive tool to investigate a class of constructions that is widely attested cross linguistically.

Impersonals

In traditional grammar, IMPERSONAL CONSTRUCTIONS are those where the verb lacks usual agreement with a subject. Often there is an overt pleonastic subject, as in the French example in (21a), or no visible subject at all, as in the Spanish example in (21b):

(21) a. Il est arrivé trois femmes. *French*
'There arrived (SG) three woman.'
b. Se vende tortillas. *Spanish*
'One sells (SG) tortillas.'

Work in RG extends the class of impersonals to include some cases where the verb does agree with some nominal – usually when the nominal occurs in what is not the usual subject position. For example, Perlmutter (1983a) analyzes post-posed subjects in Italian, such as the example in (22), as instances of impersonal constructions:

(22) Sono rimasti dei profughi ungheresi nel paese.
'There remained (PL) some Hungarian refugees in the country.' (Perlmutter, 1983a: 142)

Perlmutter argues that the superficial subject of (22) is a silent pleonastic (SILENT DUMMY); this dummy element enters the RN at a non-initial stratum, overrunning another element; hence, *dei profughi ungheresi* heads a final Cho-arc. The notion BROTHER-IN-LAW is defined as that which holds a dummy and the element it overruns. Some languages, e.g., Italian, but not French, exhibit BROTHER-IN-LAW AGREEMENT – the ability of a verb to agree with the brother-in-law of a dummy that is a final 1. Under this

account, an impersonal construction is defined as one whose final subject is a dummy. A partial RN for (22) is shown in (23):

(23)

Notice that the predicate in (23) is unaccusative – it has an initial 2-arc and no initial 1-arc. Perlmutter argues, on the basis of *ne*-cliticization, that *dei profughi ungheresi* does not advance to 1 in (23). Rather, the dummy enters as 2-arc and then advances to 1 (satisfying the Final-1 Law). Three laws limit the distribution of dummies: the Active Dummy Law (dummies must put some nominal *en chômage*), the Nuclear Dummy Law (dummies may enter as either 2-arcs or 1-arcs), and the Dummy Demotion Ban (dummies may not demote).

Other impersonal constructions discussed in Perlmutter (1983a) include IMPERSONAL PASSIVES, IMPERSONAL INVERSIONS, and IMPERSONAL UNERGATIVES. In this last case, the dummy enters as a 1-arc, putting the initial-1 *en chômage*.

Impersonal constructions have been the focus of intense research outside of RG; in particular, the analog of brother-in-law agreement (and the related issue of the Case of the overrun element – BROTHER-IN-LAW CASE in RG terms) has been central in later Principles and Parameters and Minimimalist work (e.g., Lasnik, 1995). As in RG accounts, the issue of possible links between pleonastic elements and their brothers-in-law (ASSOCIATES) is explored.

One aspect of the RG account that has been controversial has been the existence of silent dummies, because these are silent elements without semantic content. Given the Final-1 Law, silent dummies are mandated in any clause that does not have another final-1. A similar theoretical motivation exists on other frameworks that assume the equivalent of the Final-1 Law (e.g., the EXTENDED PROJECTION PRINCIPLE (EPP) in GB and the SUBJECT CONDITION in LFG). Perlmutter and Zaenen (1984) provide empirical arguments for silent dummies from a dialect contrast in Dutch, and Perlmutter and Moore (2002) do the same for Russian.

Nevertheless, impersonal constructions without overt expletives have been sometimes cited as a challenge for the Final-1 Law. For example, Babby (1989) argues for subjectless impersonals in Russian and Ukranian. Blevins (2003), working in an HPSG framework, argues for a similar position for a number of Finnic, Baltic, and Slavic languages. Finally, McCloskey (2001) proposes that silent dummies are present in some languages (e.g., Romance languages), but are absent in Irish. Thus, the issue of silent dummies and the Final-1 Law – brought into focus in RG research – remains an important topic of syntactic investigation.

Cross-Clausal Constructions

The preceding sections surveyed four constructions that are generally associated with relation changes in simplex clauses. RG has also been influential in its treatment of cross-clausal phenomena.

Perlmutter and Postal (1983a) discuss the types of RAISING CONSTRUCTIONS (ASCENTIONS) and propose the RELATIONAL SUCCESSION LAW (1983a: 53). This requires that a raisee take on the GR that was borne by the clause itself – e.g., raising from an object clause will result in an object raisee, raising from a subject clause results in a subject.

Another cross-clausal domain in which there has been considerable RG research involves UNION CONSTRUCTIONS. Often associated with causative or perception verbs, these clauses typically exhibit both bi- and mono-clausal characteristics. The RG approach to these phenomena involves a rule of CLAUSE UNION that raises all the arcs of an embedded clause into a matrix clause. Influential RG papers in this area include Aissen and Perlmutter's 1976 *BLS* paper (expanded in Aissen and Perlmutter, 1983), which examines CLITIC CIMBING in Spanish; Gibson and Raposo (1986), which explores principles that govern the GRs that the raises arcs assume under Clause Union; and Davies and Rosen (1988), which develops an alternative, mono-clausal, treatment of Clause Union.

APG

Given the DERIVATIONAL nature of Standard Theory, one might view RG as an alternative derivational framework, differing from Standard Theory only in the primitive status of GRs. Indeed, the stratal diagram representation invites such an interpretation – one might view each stratum as derived from the preceding one. However, RG relies on a REPRESENTATION interpretation; while the strata are ordered, laws and rules have access to the entire representation. For example, conditions that are stated in terms of Working-1 are necessarily META-STRATAL; that is, they take into account whether an element heads a 1-arc at any stratum. Thus, RG represented one of the first

representational, constraint-based frameworks. ARC PAIR GRAMMAR (APG) (Johnson and Postal, 1979) takes this aspect of RG as fundamental. It defines RNs corresponding to the sentences of a language in set-theoretic terms and states both laws and rules as truth-conditional statements that limit the class of possible sentences. Furthermore, the language-particular rules in APG negatively limited the class of possible sentence types. Rather than specifying that a particular language has a dative-shift rule (3 to 2 advancement, in RG terms), it assumes that all languages allow this sentence type, unless a rule specifically prohibits it. This foreshadows an aspect of Optimality Theory, which assumes a universal set of markedness constraints.

APG posits two primitive relations between arcs: SPONSOR and ERASE. Sentences are represented by PAIR NETWORKS (PNs), which resemble RG RNs, augmented with representations of the sponsor and erase relations; (24) shows a pair network for the passive clause in (4):

(24)

The curly arrows represent the sponsor relations; e.g., the initial 2-arc sponsors the final 1-arc. The double arrows represent the erase relation; e.g., the final 1-arc erases the initial 1-arc. All arcs must have sponsors; the initial arcs sponsor themselves and non-initial arcs have sponsors distinct from themselves. All arcs that are not phonologically realized must be erased. Thus, the set of unerased arcs corresponds roughly to the RG final stratum.

Formally, the PN is defined as an ordered pair; the first member consists of the sponsor relation (the set of sponsor/sponsoree pairs), and the second member is the erase relation (the set of eraser/erasee pairs). Hence, the PN in (24) is defined more formally in (25):

(25) $\langle\{\langle A,A\rangle,\langle B,B\rangle,\langle C,C\rangle,\langle A,D\rangle,\langle B,E\rangle\},$
$\{\langle D,A\rangle,\langle E,B\rangle\}\rangle$

Aside from providing a more rigorous version of RG, APG expands into empirical domains that were not the focus of most RG work. For example, APG makes use of the sponsor and erase relations to develop an account of anaphora and prepositional phrases. In the former case, two arcs headed by the same element may COSPONSOR an anaphoric arc. Only one of the two is erased by the anaphoric arc (REPLACED); the other remains as the anaphor's antecedent.

Aside from Johnson and Postal (1979), which provides detailed analysis of a wide range of constructions, major works cast in APG include Postals's treatments of passives (Postal, 1986) and Aissen's APG analysis of Tzotzil (Aissen, 1987).

Conclusion

Although work in RG and APG had virtually ceased by the 1990s, RG work has had a profound effect on theoretical linguistics. Many aspects of the framework foreshadowed later developments in other frameworks and clearly delineated several persistent theoretical issues (e.g., derivation versus representation, mono-versus multi-stratality, grammatical relations as primitive elements, universal versus language-specific principles, rule- versus constraint-based grammars). Furthermore, one finds other frameworks adopting analyses that are similar to those previously presented in GR terms (e.g., various implementations of the Unaccusative Hypothesis). In addition to these theoretical and analytical contributions, RG research made a significant empirical contribution. While cross-linguistic research was always a hallmark of generative approaches, RG was particularly good at producing detailed accounts of a wide range of languages. Much of the data originally collected and analyzed by RG practitioners has become part of the collective consciousness of theoretical linguistics.

Grammaticalization

I Wischer, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Grammaticalization (also 'grammaticization') is generally regarded as a process by which linguistic elements (lexical, pragmatic, and sometimes even phonetic items) change into constituents of grammar, or by which grammatical items become more grammatical in time. Examples are the development of auxiliaries from lexical verbs, or prepositions from nouns; the development of inflections from free adpositions; and the change of word-orders that signal pragmatic meanings, like theme or rheme, into grammatical word-orders that signal the syntactic cases of subject and object. Furthermore, it includes the functionalization/grammaticalization of phonological or prosodic features, such as palatalization and initial mutations to distinguish different cases; number and gender in Irish; or a particular tone taking over the function of a nominal classifier in Chinese. The whole concept of grammaticalization can be characterized as the diachronic process and the synchronic state of coding of grammatical categories, such as case, number, gender, tense, aspect, mood, etc. (for a general reference work cf. Hopper and Traugott, 2003).

It is widely assumed that linguistic items historically go through the following stages:

(1) free lexical unit > function word > affix > zero

The change from free lexical units to function words builds up periphrastic, or analytical, constructions. In a further step, synthetic structures can develop via cliticization, or affixation. Here simple agglutination

Relational Network Grammar

D C Bennett, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Relational network grammar (RNG) is a more general label for the linguistic theory that used to be known as stratificational grammar (SG). The latter originated in the late 1950s when Sydney Lamb combined a version of Bloomfieldian structuralism with ideas from Hjelmslev's Glossematics. RNG now operates with a much looser conception of stratification and has also undergone a considerable broadening of its goals. Even SG itself was never content to concentrate on 'competence' to the exclusion of 'performance,' preferring instead to provide an account of language that can be used to model the processes of speech production and comprehension. However, besides this feature of the theory, referred to now (Lamb, 1999: 293) as the requirement of 'operational plausibility,' two further requirements have been added: those of 'developmental plausibility' and 'neurological plausibility' (1999: 293) – i.e., that a realistic theory should (a) provide a plausible account of how the proposed linguistic system can be learned, and (b) be compatible with what is known about the brain from neurology and cognitive neuroscience. The remainder of this article is divided into four sections. The first section presents details of SG; the second discusses language as a network of relationships; the third mentions the relationship between complex lexemes, constructions, and syntax; and the fourth expands on operational, developmental, and neurological plausibility.

Stratificational Grammar

Tactics vs. Realization

The Bloomfieldian model of language of Hockett (1955: 14) contained three central subsystems: phonology, grammar, and morphophonemics. The phonology and grammar crucially incorporated a mechanism for specifying possible combinations of phonemes and morphemes respectively. In the case of phonology this was referred to as the 'phonotactics,' and the '-tactics' part of this term formed the basis of such later coinings as 'morphotactics,' 'lexotactics' and 'semotactics.' Hockett's (1955) 'grammar' subsystem was in effect a morphotactics. The morphophonemic subsystem, on the other hand, had a different function, in that it characterized the representation – or 'realization' – of morphemes in terms of phonemes, and therefore formed a bridge between grammar and phonology. Hockett's (1955) model was equivalent to a two-stratum SG.

One of the two main features that SG derived from Glossematics was its concern with 'content' as well as 'expression' (Hjelmslev, 1961: 47–60, 66–67, 70–72). This entailed an immediate increase in the number of strata recognized. (For the other main feature from Glossematics, see 'A Network of Relations' below.) During the 1960s, 1970s, and 1980s, the number of strata posited was under continuous review, but the four-stratum model of Figure 1 was commonest (Gleason, 1964; Lamb, 1964, 1971). Evidence in support of stratal distinctions was of two kinds, tactic and realizational. Tactic evidence will be discussed in 'Independent Patterning' below. Realizational evidence consisted in identifying examples of the same

Figure 1 A four-stratum stratificational grammar.

realizational relationships at different levels of the content-to-expression dimension. Thus 'composite realization' is illustrated both by *bet* (realized as the phoneme sequence /b/ + /e/ + /t/) and by *understand* (realized as the morpheme sequence *under* + *stand*) – the first involving morphophonemic structure, the second lexomorphemic structure. Similarly, the alternation between *a* and *an* (as in *a lemon* vs. *an orange*) involves the same relationship as that between *although* and *despite* (as in *although he was tired* vs. *despite his tiredness*) – the former morphophonemic and the latter semolexemic.

Independent Patterning

It is generally accepted that language exhibits 'duality' of patterning (Hockett, 1958: 574–575), and the claim that phonotactic patterning is independent of syntactic patterning is therefore uncontentious. Similarly, other approaches than SG have also treated syntax and morphology as separate modules. Less obvious, perhaps, is the claim that syntax and semantics involve separate tactic patterns – the lexotactics and semotactics (whose smallest constituents are 'lexemes,' or lexical items, and 'sememes'). The nature of the difference between them can be indicated particularly clearly in relation to sentences that describe a change of location. Such sentences may contain a 'source expression,' a 'path expression,' and a 'goal expression':

(1) We drove from York over the Pennines to Manchester.

However, what is involved here is not a syntactic distinction between three kinds of prepositional phrases (PPs) but a semantic distinction that cuts across syntactic categories such as 'preposition' and 'verb.' In (1) the goal expression *to Manchester* is realized as a PP, but there are goal expressions also in (2) and (3) – realized as *enter the stadium* and *appear*, respectively:

(2) The first runner is just about to enter the stadium.
(3) Suddenly a rabbit appeared from behind the hedge.

Similarly, 'means of locomotion' is a semantic rather than a syntactic category, and the same means of locomotion constituent that is realized in the verb *drive* in (1) is realized as the PP *by car* in (4). Moreover, sentences such as (5) demonstrate that the means of locomotion constituent is optional. A verb, on the other hand, is obligatory in such sentences – cf. (6).

(4) We went to Manchester by car.
(5) From here I shall go straight home.
(6) *We to-ed Manchester by car.

Further light is thrown on the distinction between lexotactics and semotactics (a) by sequences of PPs and (b) by examples of prepositions governing a PP rather than a noun phrase. The difference in structure between (directional) *from York over the Pennines to Manchester* and (locative) *in a box under the table near the window* is characterized in the semotactics, and this leaves the lexotactics free to generate arbitrary sequences of PPs without regard to their semantic structure. The difference in grammaticality between *from behind the door* and **from to the door* is, again, a matter of their semotactic structure, which means that the lexotactics can be maximally general and allow any preposition to govern any PP.

A Network of Relations

Tactic Networks

The view of language as a network of relations was present in Saussure (1949: 170) but was even more prominent in Hjelmslev (1961: 23), from where it was taken into SG. Lamb's network notation was based on Halliday's notation for systemic networks (Lamb, 2004: 32–33). To introduce the notation, we may take a simple phrase structure grammar (PSG) and convert it into network form. The PSG in (7) represents a highly simplified fragment of English lexotactics, incorporating some of the information about PPs discussed in 'Independent Patterning' above.

Figure 2 Separate networks corresponding to the five PS rules in example (7).

(7) S → NP V (NP) (PP)
NP → Det N (S)
V → {*enter*, *arrive*, *drive*, *go*, . . .}

$$\text{PP} \rightarrow \text{prep} \left\{ \begin{matrix} \text{NP} \\ \text{PP} \end{matrix} \right\} (\text{PP})$$

prep → {*to*, *into*, *at*, *in*, . . .}

Figure 2, parts (**A**)–(**E**), converts each of the five rules of (7) into the form of a separate network, in which triangular nodes – symbolizing the AND relationship – represent the S, NP, and PP constructions, and the remainder of the nodes are examples of the OR relationship. The ANDs are, specifically, downward ordered ANDs, i.e., they branch in the downward direction and the left-to-right sequence of the lines on the 'plural' side of the node represents the order in which the constituents in question occur. The ORs are also all downward nodes. Two of them – see parts (**D**) and (**E**) – represent the categories V and prep, and they are unordered – i.e., the lines on the plural side of the node, representing members of the category, connect to the same point. There is one further unordered OR – in part (**C**) – representing the choice between a NP and a PP as object of a preposition. The remainder of the downward ORs in Figure 2 represent the optionality of some constituent, i.e., there is a choice between the constituent in question and zero. Moreover, the zero alternative is treated as the default option, which is selected unless the other possibility takes precedence over it. The default option, in this case the line ending in a small circle (representing zero), is shown as the continuation of the line from the 'singular' side of the node. The other line from the plural side is offset from the center of the node. This type of OR node is an ordered OR but the ordering is one of priority, or precedence, rather than sequence.

Comparison of parts (**A**) and (**D**) in Figure 2 reveals two occurrences of the symbol 'V,' indicating that one of the four lines at the bottom of (**A**) is in fact the same line as the one at the top of (**D**). This can be made explicit by connecting the top of network (**D**) to the appropriate place at the bottom of network (**A**). In the same way, the 'prep' line at the top of network (**E**) can be connected to the corresponding line at the bottom of (**C**). The symbols 'V' and 'prep' are then redundant. It is customary to write them alongside the relevant lines in the diagram to aid a reader in interpreting it (see Figure 3). However, the combined network conveys the same information whether these labels are present or absent. The crucial labels are those on the lines at the outer edges of the network, since these indicate where it belongs in some even larger network.

The situation with regard to the symbols 'S,' 'NP,' and 'PP' requires the use of a new type of node, an upward unordered OR. Corresponding, for instance, to the 'NP' at the top of Figure 2(**B**), there are two occurrences of 'NP' at the bottom of (**A**) and one occurrence at the bottom of (**C**). While (**B**) represents the internal structure of an NP, (**A**) and (**C**)

Figure 3 The combined network corresponding to Figure 2 (**A**)–(**E**).

together show three separate functions of an NP. Figure 3 – which results from connecting together all five networks of Figure 2 – therefore incorporates an upward OR above the line labeled 'NP,' with lines connecting to the three slots in question. Any given NP is functioning **either** as the subject of a sentence, **or** as the object, **or** as the object of a preposition. In a similar way, there are upward ORs also above the 'S' and 'PP' lines in Figure 3.

Integrating Tactics and Realization

Figure 4 integrates the lexotactics of Figure 3 with fragments of realizational structure corresponding to particular members of the categories V and prep. The diagraming convention for the realizational structure is that meaning is located at the top and speech at the bottom. Tactic patterns are thought of as horizontal and as intersecting with the realizational structure. This is why the lexotactics is drawn on its side in Figure 4, compared with Figure 3. The diamond-shaped nodes in Figure 4 are used where lines in the realizational structure intersect with the lexotactics. They are a special kind of AND node; the lexeme *into*, for instance, has a particular meaning (indicated in the upper half of the diagram) **and** a particular pronunciation (shown, in part, in the lower half of the diagram) **and** a particular lexotactic distribution (see further Lockwood, 1972: 55–58).

The realizational structure in Figure 4 makes use of two additional types of node. An unordered upward AND indicates that a particular combination of sememes is realized in a particular way lexemically, e.g., that the combination of 'locative' and 'interior' may be realized as the lexeme *in*. An unordered downward AND is used to show that the phoneme /n/ , which occurs in *enter* and *in*, is realized as a (simultaneous) combination of the phonological components /Apical/ and /Nasal/.

Other tactic patterns could be added to Figure 4. For instance, a semotactics would specify the distribution of sememes such as 'goal,' 'locative,' and 'interior' – showing, for instance, that 'goal' is related syntagmatically to 'source' and 'path'; that source, path, and goal expressions all contain a locative expression; that locative expressions may themselves incorporate a directional expression, as in (8); and that 'interior' is related paradigmatically to such sememes as 'surface,' 'anterior,' and 'posterior' (see further Bennett, 1975: 132–176; 1997: 135–140).

(8) The ticket office is through that archway.

A morphotactics and phonotactics could also be added at appropriate levels of the lower part of Figure 4.

Further Properties of the Overall Network

Adopting the 'looser conception of stratification' that was referred to in the introduction, the view that language has a fixed number of strata was abandoned in favor of the view that some parts of a linguistic system may be stratified to a greater extent than others. What now seems fundamental is merely the broad three-way distinction between the phonological, lexicogrammatical, and conceptual systems.

The conceptual system forms a bridge between linguistic structure narrowly defined and the various perceptual systems. The concept 'cat,' for instance, is connected not only to the lexeme *cat* in the linguistic system and to other concepts representing information about cats, but also has connections to visual, auditory, and tactile perception. A person's knowledge of cats includes knowing what they look like, what sounds they make, and what their fur and claws feel like. Consideration of the perceptual systems forces a reassessment of the bottom-to-top dimension of linguistic structure. At the 'bottom' of linguistic structure are the separate interfaces with the world for speech perception and phonetic articulation. These are at the lowest level of the linguistic structure. There are also interfaces with the world for the various perceptual modalities, e.g., the retina of the eye; and just as there are higher (more abstract) levels of linguistic structure, so also there are higher levels of the perceptual systems. Concepts integrate the linguistic structure with the perceptual systems, and are

Figure 4 Integrating a fragment of lexotactics with some realizational structure.

therefore at the top of each – in which case the whole cognitive structure may be thought of as forming an arch (Lamb, 1999: 121–125).

A 'nection' (formed from the word 'connection,' and described as the "first significant level of organization above that of the elementary relations" [Lamb, 1984: 76]) is a configuration of lines and nodes with one line – called the 'nection center' – connecting the singular side of one node to the singular side of another node. (For a more technical definition, see Lamb, 1999: 72–77.) It branches in two directions and, in the realizational structure, has a content-oriented side and an expression-oriented side. (The same is true, in fact, of nections in tactic

patterns – see 'Complex Lexemes, Constructions, and Syntax' below.) As examples of nections we may consider one configuration of nodes and lines from near the bottom of Figure 4 and another from near the top. Near the bottom there is a nection corresponding to the phoneme /n/. The unordered downward AND below the nection center shows the composition of this phoneme as a particular bundle of phonological components; and the unordered upward OR above the nection center has connections on its (upper) plural side corresponding to occurrences of the phoneme /n/ in particular morphemes. Near the top of Figure 4 there is an unordered upward AND from which lines travel upwards towards the sememes 'locative' and 'interior'; and the line on the singular (= lower) side of this upward AND connects also to the singular (= upper) side of an ordered downward OR. One line from the plural side of this OR node represents the default realization of the combination of sememes in question – as the lexeme *in*. The other line leads towards nections corresponding to semantically more complex lexemes such as *into* and *enter*.

Nections are the relational or cognitive units corresponding to Saussure's 'signs' (Lamb, 1987, 2004: 415–424) – but with the proviso that, rather than there being just a single level of signs, linguistic structure is made up of a whole hierarchy of signlike relationships, in which the content side of the lower-level nections involves connections upwards towards conceptual structure rather than meaning as such.

Complex Lexemes, Constructions and Syntax

Besides the independently existing lexemes *happy* and *-ness*, the lexicon of a typical speaker will also contain a higher nection for the complex lexeme *happiness*: "any two things that occur consistently together are likely to become associated" (Lamb, 1999: 271). Moreover, "it is repeated use rather than degree of idiomaticity that determines presence or absence of a higher-level lexical nection" (Lamb, 1999: 165). Admittedly, many complex lexemes are idiomatic to a greater or lesser degree, e.g., *kick the bucket*, *at the end of the day*; however, many complex lexemes are nonidiomatic fixed expressions. Some complex lexemes are also quite complex syntactically, e.g.: *no laughing matter*; *the truth of the matter is…*; *take…for granted*; *If it ain't broken, don't fix it*. Occasionally a complex lexeme comes into existence on the basis of relatively few occurrences if it attracts enough attention, e.g., *the mother of all battles* (the English translation of something said in Arabic by Saddam Hussein). Such an expression may then be the model for parallel expressions, as when a pilot who witnessed a particular meteor described it as *the mother of all meteors* – at which point we are dealing with a "mutable lexeme" (Lamb, 1999: 264–265): *the mother of all* <THING>*s*, i.e., a complex lexeme that contains a variable constituent. Other mutable lexemes may contain two or more variables, e.g., *you don't have to be a* <X> *to* <Y> *that* <ASSERTION> (where *brain surgeon* and *understand* would be obvious values for X and Y). The limiting case is that of a construction in which all the constituents are variable, e.g., the 'caused motion' construction illustrated by *Frank sneezed the tissue off the table* (Goldberg, 1995: 152–79), where it is the schema of the construction as a whole that conveys the 'caused motion' interpretation.

Construction grammar (e.g., Goldberg, 1995; Kay and Fillmore, 1999) has provided detailed analyses of a wide range of constructions, and has shown which syntactic and semantic properties of an idiomatic construction are peculiar to that construction, and which properties are contributed by more general constructions of core grammar. By contrast, RNG has had relatively little to say about constructions. However, the notion of constructions fits naturally into the RNG framework. In a relatively early discussion of language as a system of signs, Lamb (1984: 80–85) advocated general recognition of constructional meanings and posited connections towards conceptual structure in both the realizational structure and tactic patterns. More recently, Lamb (2004: 298–317) discussed the role of constructions in the child's acquisition of syntax and concluded, *inter alia*, that syntactic knowledge is associated with individual lexical items (rather than general categories) and is widely distributed, among thousands of separate items.

Whereas Lamb (1984: 80–85) used unordered upward AND nodes in indicating the constructional meanings of particular tactic configurations, Figure 5 uses a DIAMOND node – for easier comparison with the nections for lexemes that feature in Figure 4. The DIAMOND nodes in Figure 4 are all located at the bottom of the lexotactics, on lines corresponding to individual lexemes such as *enter*, *arrive*, *to*. The nodes in question have connections at top left (towards conceptual structure), at bottom right (towards phonology and phonetics), and at top right (into the lexotactics). As an example of a tactic nection we may consider the NP nection from Figure 4. This consists of the configuration of nodes and lines which shows the (highly simplified) internal structure of a NP together with the alternative functions it fulfils within the lexotactics. Assuming that some part of the meaning of a NP comes from the construction

Figure 5 The NP connection in the lexotactics.

as a whole rather than its internal constituents, its connection towards conceptual structure can be shown as in Figure 5. The DIAMOND in question has a connection at top left (towards conceptual structure) and at top right and bottom left to higher and lower in the tactics. There is a connection at bottom left rather than bottom right, because the meaning in question is realized as the NP construction rather than as an individual lexeme with a particular phonological representation. Such DIAMOND connections may be situated at any appropriate place in a tactics, even at the top if the largest construction specified by the tactics has its own constructional meaning.

Operational, Developmental and Neurological Plausibility

Operational Plausibility

The information in a linguistic system is crucially utilized in the processes of speech production and comprehension; and a major advantage of RNG is that it represents linguistic knowledge in a form in which it can be directly operated on. This involves the activation of the network by signals, which (broadly speaking) travel downwards for production and upwards for comprehension. Various kinds of linguistic evidence provide insights into necessary properties of the signaling. Lamb listed 13 (2004: 331–335), of which three will be briefly mentioned here: slips of the tongue, prototype effects, and an example of "on-line cognitive processing in conversation."

Dell and Reich (1980) summarized what is known about slips of the tongue from extensive analysis of data; and then discussed the findings of their RNG computer simulation of how slips might arise in the speech production process. The simulation replicated the major varieties of slips found empirically and their relative frequencies, e.g., that anticipation errors outnumber perseveration errors. It also mirrored the interaction between the 'lexical editing effect' and speaking rate. Specifically, errors resulting in words outnumbered errors resulting in nonwords at the slowest speaking rate, but at the fastest speaking rate errors resulting in nonwords were much more frequent. The simulation used a range of values of 'activation' in the network and allowed some proportion of the signal at a given node to spread to all neighboring nodes (both above and below the node in question) at each successive time step. At the slower speaking rates, such 'spreading activation' reverberates between word nodes and their constituent phoneme nodes, making the sequence of phonemes in question more likely to occur in the output. By contrast, the activation of a sequence of phonemes that lacks a corresponding word node tends to die away over time and such a sequence is therefore less likely to occur in the output. At the faster speaking rates, there is less time for such reverberation to take place, and consequently less time to edit out nonword strings of phonemes. Another important feature of the model is the notion of 'competition': wherever at some point in the production process two or more items are competing to occur, the one with the higher or highest level of activation is chosen. Finally, the model suggested a number of testable predictions.

Nections for concepts, e.g., the concept 'cup,' are connected to nections representing their individual properties. In production (as opposed to comprehension), the concept 'cup' is activated, and the lexeme *cup* may be used, if enough of the more important properties of cups are present in the speaker's situational context. In this case the activation of the nection for the concept 'cup' exceeds its threshold value. The set of properties of cups, and their relative importance, varies to some extent from speaker to speaker, since people may have had different experience with cups – e.g., some speakers may not have encountered Japanese handleless porcelain cups. Shape and function are in general very important, i.e., cups taper towards the bottom and are typically used for drinking. 'Having a handle' is characteristic – though, quite apart from the Japanese cups mentioned above, there is a correlation between 'having a handle' and material, in that plastic cups from a drinks machine do not have a handle. It is assumed that all such information is represented in the cognitive networks of individual speakers. Moreover, connections for individual properties are of varying strengths depending on their relative importance (Lamb, 1999: 208); and "those properties which are most often experienced in connection with a category will become ever more salient" (1999: 226). This is because "the pathways of the brain are like pathways through a meadow or field or jungle – the more they

are used the easier they become to use again" (1999: 179). This means that the network automatically accounts for prototypicality phenomena without any additional theoretical equipment (1999: 226). It responds more strongly and rapidly to prototypical members of a category than peripheral ones, because they activate the most and the strongest connections to properties.

Example (9), reported by Lederer (1987), is an actual courtroom exchange:

(9) Attorney: *Mrs. Jones, is your appearance here this morning pursuant to a deposition notice which I sent to your attorney?*
Witness: *No. This is how I dress when I go to work.*

Summarizing Lamb's (1999: 202–203, 2004: 334–335) discussion of (9), the important details are that (a) *appearance* is ambiguous and (b) the witness chooses the wrong sense, because (c) she was probably already concerned about how she looks and (d) the phrase *pursuant to a deposition notice*, being no doubt unfamiliar to her, probably did not generate much activity in her conceptual system.

The above three kinds of evidence suggest that the signaling system needs: (i) to make use of spreading activation and the notion of competition (which in turn imply different degrees of activation); (ii) to operate with connections of different strengths and threshold values that nodes need to reach before they "fire"; and (iii) to allow linguistic processing to be affected by (weak) signals representing a speaker's general beliefs and concerns. This last factor is involved also in so-called Freudian slips (Dell and Reich, 1980: 23) and in 'unintended puns' (Reich, 1985).

In addition, definitions need to be provided for the various kinds of node that feature in the networks of Figures 2–5, so that signaling passes through the network in the appropriate way. Lamb's (1999: 77–83, 97–102, 134–136, 249–251) general approach involves replacing the earlier notation (which is now referred to as 'compact notation') by a more precise and explicit 'narrow notation,' designed to reveal the internal structure of nodes. Figure 6 provides a very simple example of a nection using compact notation and the corresponding two nections in narrow notation. Compact notation was always regarded as bidirectional. However, the nection in part (**A**) of Figure 6 needs to behave differently in the downward and upward directions; and this fact is made explicit in (**B**) and (**C**), where (**B**) is for 'downwards' and (**C**) for 'upwards.' The two types of nodes occurring in the narrow notation of Figure 6 (**B**) and (**C**) are referred to as the 'branching node,' drawn as a tiny solid circle, and the 'junction,' drawn as a larger hollow circle. In both directions, for this example, signals enter the

Figure 6 (**A**) A simple nection in compact network notation. (**B** and **C**) The corresponding downward and upward nections in narrow notation.

nection via a junction and leave via a branching node. The branching node of Figure 6 (**B**) behaves in the same way as that of (**C**), sending out activation along all the available lines – despite the fact that the one in (**B**) corresponds to an AND in (**A**) whereas the one in (**C**) corresponds to an OR. When activation travels through an OR node from the singular to the plural side, it behaves like an AND node, because at the OR itself there is no way for it to know which line to take, the choice between the alternatives being determined further along (Lamb, 1999: 68–69).

The earlier discussion of the concept 'cup,' and concepts generally, invoked the notion of a 'threshold node.' For a concept to 'fire,' in the production direction, enough of its properties need to be activated. The node is a compromise between an AND and an OR, in that it allows some combination of properties to be present but does not require them all to be present (Lamb, 1999: 153–156). In the narrow notation, the AND and OR nodes of the compact notation are treated, in the plural-to-singular direction, as special cases of the threshold node and represented as a junction with a particular threshold value – 1 for the OR, and for the AND a value equal to the number of lines on the plural side of the node. In Figure 6(**B**), as soon as activation reaches the junction along **one** of the lines 'P_d' or 'Q_d,' it continues on downwards to the branching node leading to 'X_d' and 'Y_d.' In Figure 6(**C**), on the other hand, activation has to reach the junction along **both** 'X_u' **and** 'Y_u' before it may proceed upwards to the branching node leading to 'P_u' and 'Q_u.'

Other nodes are rather more complex than those of Figure 6(**A**). One proposal for the ordered OR involves using an 'inhibitory connection' to block the default line when the conditions for the precedence line are activated (Lamb, 1999: 80–81). Ordered AND nodes need to specify sequencing of constituents, which requires keeping activation alive for a while and then turning it off. Coming up with proposals that work is by no means trivial – see Lamb (1999: 97–101, 135–136, 249–251).

Developmental Plausibility

The 'operational' vs. 'developmental' distinction is broadly equivalent to 'using' vs. 'building' a relational network. However, the comprehension process involves not just recognizing lower-level linguistic nections but also adding structure to the listener's cognitive network by way of integrating newly acquired information into the existing body of knowledge (Lamb, 1999: 196–199, 2004: 277–297).

RNG assumes that the network of the linguistic system starts out containing a vast number of latent nections, each of which has a large number of latent connections to other nections (Lamb, 1999: 321–322). Learning consists in recruiting nections for particular functions by strengthening a subset of their connections to other nections. Many of the connections that get established in this way are local within a particular part of the linguistic system. However, long-distance connections are also needed in, say, the recruitment of a nection for integrating particular conceptual and perceptual information (1999: 176–179).

Neurological Plausibility

RNG's view of language as a relational network is compatible with the neural network structure of the cerebral cortex. Secondly, the learning hypothesis in 'Developmental Plausibility' above is compatible with the fact that no new neurons are formed in the human brain after birth (Lamb, 1999: 322). Thirdly, the fact that phonological production is controlled from Broca's area of the brain, whereas phonological perception is located in Wernicke's area, suggests that there are separate phonological systems for production and perception. In general, though, previously determined properties of linguistic data have suggested predictions about the brain, rather than that properties of the brain were built into RNG from the outset. Areas of convergence between RNG and neuroscience include: unidirectional signaling, thresholds, inhibitory (as well as excitatory) activation, and degrees of activation. As for nection–brain correspondences, Lamb has hypothesized that a nection might correspond to a bundle of several cortical 'minicolumns' (2004: 322). As further advances take place in neuroscience, aided by improvements in brain-imaging techniques, RNG hopes to remain at the forefront of cooperation between the two fields.

Relations and Functions

H van de Koot, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Functions and other relational notions play a role in linguistic theory at various levels of grammatical organization.

In many linguistic theories (e.g., Relational Grammar, Systemic Grammar, Functional Grammar, Lexical-Functional Grammar, and Word Grammar), a grammatical description of a sentence distinguishes between a constituent's form (its syntactic category) and its syntactic function, such as SUBJECT or OBJECT. The grammatical function of a constituent classifies it in terms of its relation to other elements and determines various aspects of its syntactic behavior, such as the position that it occupies and whether it enters into syntactic processes such as agreement, passivization, and reflexivization. For example, in English, the constituent that functions as the SUBJECT of a sentence typically precedes the verb and – in a tensed clause – agrees with it.

The syntactic functions of a constituent must be distinguished from its semantic function, which defines the participant role (such as Agent, Theme, Patient, Source, or Goal) that it plays in the state of affairs expressed by the sentence. Thus, in both (1) and (2), the constituent *John* has the semantic function of Patient. But in (1) it is the OBJECT of the sentence (realized postverbally), while in its passive counterpart (2) it is the SUBJECT (and hence realized preverbally).

(1) Susan fired John.

(2) John was fired (by Susan).

Indeed, in a theory based on grammatical functions, processes such as passivization or reflexivization make direct reference to functions. In Lexical Functional Grammar, for example, passivization involves a remapping between participant roles and grammatical functions: while in active sentences the Agent is mapped to the syntactic function of SUBJECT and the Patient to that of OBJECT, the latter participant role is mapped to the syntactic function of SUBJECT in the passive voice (while the Agent either remains unexpressed or is mapped to an oblique form – a *by*-phrase in English). When the Patient role is mapped to the SUBJECT function, it shows up in the canonical position for SUBJECTS, as shown in (2).

Figure 1 Movement.

By contrast, in a theory of grammar that lacks grammatical functions or similar relational concepts, such as Government and Binding theory, the participant role of Patient is mapped to the same structural position in both (1) and its passive variant in (2). This implies that *John* in (2) originates as the complement of the verb and undergoes movement to the position occupied by *Susan* in (1), as in Figure 1.

There is also a more technical, mathematical interpretation of 'function' and 'relation' that plays a role in formal semantics. A mathematical relation maps elements of one set to elements of another. A relation may be one-to-one (e.g., plus–1), many-to-one (e.g., born-of) or one-to-many (e.g., mother-of). A mathematical function is a restricted kind of relation that is either one-to-one or many-to-one, but not one-to-many.

Relative Clauses

I Nikolaeva, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Definition

The relative clause (RC) can be defined as a modifying clause. The following semantic types of clausal modification are usually distinguished. The so-called restrictive RCs modify a nominal whose semantic function consists in establishing a set of entities referred to as the domain of relativization (Keenan and Comrie, 1977; Keenan, 1985). The RC identifies a certain subset of this domain. For example, in (1)

(1) the dog [(that/which) you saw] belongs to John

the domain of relativization is established by the modified noun *the dog*, whereas the RC indicated here with square brackets restricts this semantic

Relations and Functions

Functions and other relational notions play a role in linguistic theory at various levels of grammatical organization.

In many linguistic theories (e.g., Relational Grammar, Systemic Grammar, Functional Grammar, Lexical-Functional Grammar, and Word Grammar), a grammatical description of a sentence distinguishes between a constituent's form (its syntactic category) and its syntactic function, such as SUBJECT or OBJECT. The grammatical function of a constituent classifies it in terms of its relation to other elements and determines various aspects of its syntactic behavior, such as the position that it occupies and whether it enters into syntactic processes such as agreement, passivization, and reflexivization. For example, in English, the constituent that functions as the SUBJECT of a sentence typically precedes the verb and – in a tensed clause – agrees with it.

The syntactic functions of a constituent must be distinguished from its semantic function, which defines the participant role (such as Agent, Theme, Patient, Source, or Goal) that it plays in the state of affairs expressed by the sentence. Thus, in both (1) and (2), the constituent *John* has the semantic function of Patient. But in (1) it is the OBJECT of the sentence (realized postverbally), while in its passive counterpart (2) it is the SUBJECT (and hence realized preverbally).

(1) Susan fired John.

(2) John was fired (by Susan).

Indeed, in a theory based on grammatical functions, processes such as passivization or reflexivization make direct reference to functions. In Lexical Functional Grammar, for example, passivization involves a remapping between participant roles and grammatical functions: while in active sentences the Agent is mapped to the syntactic function of SUBJECT and the Patient to that of OBJECT, the latter participant role is mapped to the syntactic function of SUBJECT in the passive voice (while the Agent either remains unexpressed or is mapped to an oblique form – a *by*-phrase in English). When the Patient role is mapped to the SUBJECT function, it shows up in the canonical position for SUBJECTS, as shown in (2).

Figure 1 Movement.

By contrast, in a theory of grammar that lacks grammatical functions or similar relational concepts, such as Government and Binding theory, the participant role of Patient is mapped to the same structural position in both (1) and its passive variant in (2). This implies that *John* in (2) originates as the complement of the verb and undergoes movement to the position occupied by *Susan* in (1), as in **Figure 1**.

There is also a more technical, mathematical interpretation of 'function' and 'relation' that plays a role in formal semantics. A mathematical relation maps elements of one set to elements of another. A relation may be one-to-one (e.g., plus–1), many-to-one (e.g., born-of) or one-to-many (e.g., mother-of). A mathematical function is a restricted kind of relation that is either one-to-one or many-to-one, but not one-to-many.

Relative Clauses

I Nikolaeva, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Definition

The relative clause (RC) can be defined as a modifying clause. The following semantic types of clausal modification are usually distinguished. The so-called restrictive RCs modify a nominal whose semantic function consists in establishing a set of entities referred to as the domain of relativization (Keenan and Comrie, 1977; Keenan, 1985). The RC identifies a certain subset of this domain. For example, in (1)

(1) the dog [(that/which) you saw] belongs to John

the domain of relativization is established by the modified noun *the dog*, whereas the RC indicated here with square brackets restricts this semantic

domain by specifying which dog is meant. Since the restrictive RC narrows the concept associated with the modified noun, it serves the purpose of identifying the entity.

By contrast, nonrestrictive (or appositive) RCs do not serve for identification and do not restrict the reference of the nominal they modify. An example is (2).

(2) John, [who is a good teacher], got a new job

In (2) the speaker assumes that the addressee can identify the referent of the modified noun *John*. The purpose of the RC is to provide further background information about an entity whose reference is independently established.

Restrictive RCs are crosslinguistically more common than nonrestrictive ones: there are no languages with only nonrestrictive RCs, but the reverse is not true. Most languages do not show significant distinctions in the surface expression of restrictive and nonrestrictive headed relatives, although they may differ prosodically: nonrestrictives normally involve an intonational break, as is also typical of appositions and parentheticals. In English nonrestrictives, unlike restrictives, do not allow the complementizer *that* or a zero complementizer, may not stack or attach to certain quantified heads, and differ with respect to the licensing of negative polarity items. In some languages, restrictive and nonrestrictive clauses have a consistently different surface structure. For example, in Persian the suffix-*i* can only be hosted by the head of a restrictive relative. In Somali the nonrestrictive clause is preceded by the conjunction *oo*, whereas the restrictive clause is not.

Some authors (Carlson, 1977; Grosu, 1994; Grosu and Landman, 1998) additionally distinguish a third semantic type of RC, amount or degree relatives, exemplified in (3).

(3) we will never be able to recruit the soldiers [that the Chinese paraded last May]

The RC in (3) is said to contain a phonetically null element designating a quantity or amount, so that the clause can be paraphrased as *as many soldiers as the Chinese paraded last May.* At least in English, degree relatives show restrictions in the determiners and relativizers that combine with them, and differ from restrictives in their stacking possibilities.

The definition of the RC given above is essentially functional. From a syntactic viewpoint, the prototypical RC construction consists of a head and a modifying part. The referent of the head is involved in the situations expressed both by the main clause (*The dog belongs to John* in (1)) and by the modifying clause. Restrictive RCs are headed by common nouns, whereas nonrestrictive RCs can modify personal pronouns and proper nouns, see (2). By contrast, nonrestrictives are generally unavailable for nominals combined with negative and indefinite determiners.

Certain types of clauses functionally comparable to prototypical RCs may not have an obvious syntactic head. Depending on one's analysis, they are either headless or contain a phonologically empty head (see below). Some examples of apparently headless relatives are provided in (4).

(4a) [whatever you say] is wrong
(4b) he arrived late, [which I didn't like]

Such clauses serve for concept formation rather than identification and are referred to as free relatives. The domain of relativization is the class of objects of which it makes sense to assert the RC. With respect to their external syntax, free relatives fulfil a number of syntactic functions, not necessarily limited to modifying a noun. Example (4b) shows that the domain of modification may correspond to the whole clause (*he arrived late*).

Although the modifying part of the relative construction expresses a proposition, it does not necessarily have a clausal status, so in this sense the term 'relative clause' may be misleading. In a large number of languages, RCs are structurally deranked in that they do not fully resemble main/independent clauses and demonstrate some degree of nominalization. In particular, participial constructions in European languages such as *the book written by me* conform to the functional definition of the RC but are not clauses from a syntactic viewpoint. Some languages have no clear distinction between RCs and attributive modification, so that RCs and what can be referred to as adjectives show identical patterns.

All or most languages exhibit RCs of some kind. Possible exceptions are provided by languages such as Walbiri, which has a fairly general subordinating construction that allows several readings. When it contains an argument coreferential to a noun in the main clause, it can modify this noun, but it also expresses adverbial subordination, e.g.,

(5) ŋatʲlu-ɭu-ɳa yankiri pantuɳu
I-ERG-AUX emu speared
[kutʲa-lpa ŋapa ŋaɳu]
CONJ-AUX water drank
(a) 'I speared the emu that was drinking water.'
(b) 'I speared the emu while it was drinking water.'

In other words, there is no clausal construction the sole semantic purpose of which would consist in modification.

Typology

RCs exhibit remarkable structural diversity across languages and have played a prominent role in linguistic typology. The crosslinguistic taxonomy of RCs is based on three commonly accepted diagnostic criteria used for classification.

First, RCs are classified according to the syntactic relationship between the RC and its semantic head. A RC that does not form a syntactic constituent with the modified nominal is adjoined to the main clause. For example, if the Walbiri sentence (5) in the reading (5a) is to be analysed as a RC, the semantic head 'emu' and the RC do not form a larger NP. Instead the clauses are only loosely joined together. The common type of adjoined RCs are the so-called cor(r)relative constructions where the modified noun is represented as a full noun phrase both inside and outside the RC, as in the following example from Hindi.

(6) [jis a:dmi ka kutta bema:r hai],
CORELATIVE man GEN dog sick is
us a:dmi ko mai ne dekha
that man OBJ I ERG saw
'I saw the man whose dog is sick (lit. Which man's dog is sick, that man I saw)'

In (6) the noun that determines the domain of relativization ('man') is present inside the RC accompanied by the correlative marker *jis*. At the same time, it is referred to by a full anaphoric NP in the main clause.

If a RC forms a constituent with the modified nominal, it is syntactically embedded. Embedded RCs are by far the most frequent type and are divided into externally headed and internally headed. In externally headed clauses the modified noun is located outside the RC and forms a larger NP with it. If the RC follows the external head as in (1), the respective clause is called postnominal. If the RC precedes the external head, it is prenominal. The prenominal RC is illustrated by the following Finnish example.

(7) [minun teke-mä-ni] villatakki
I.GEN make-PART–1SG sweater
'the sweater (that) I made'

As has been shown in a number of typological works (Greenberg, 1963; Mallison and Blake, 1981; Keenan, 1985; Dryer, 1991), the position of the RC with respect to its external head largely correlates with the basic word order patterns of the language. Generally speaking, verb-initial and verb-final languages favor postnominal and prenominal RCs, respectively. Verb-medial SVO languages are more similar to verb-initial than to verb-final languages, as far as RCs are concerned: they prefer postnominal relatives. Thus, as already noticed by Keenan (1985: 143–144), there is a general crosslinguistic tendency in favor of postnominal RCs over the prenominal ones. In fact, in Dryer's (1991) material prenominal RCs are less common even in verb-final languages. There are various explanations of these patterns of word order in the typological literature, mainly referring to processing considerations (e.g., Kuno, 1974; Mallison and Blake, 1981; Dryer, 1992).

Internally headed RCs are found in such (predominantly verb-final) languages as Hittite and Bambara, as well as in Indic, Tungus, Hokan and Quechuan languages. In internally headed RCs, the modified noun is located inside the RC itself. Consider (8) from Udihe.

(8) si anda-i ŋene:-ni
you friend-2SG went-3SG
[bi ag'a-i xoton-du bagdi:-tigi-ni]
Ibrother–1SG city-LOC living-LATIVE-3SG
'Your friend went to the city where my brother lives.'

In (8) the semantically modified noun is 'the city.' It is located within the RC shown in brackets and hosts the Locative case marker indicating its syntactic role in the clause. As in other languages with internal relatives, there is evidence that the RC is actually a NP: in (8) the verb of the RC is nominalized and takes the Lative case which expresses the syntactic relation between the modified noun and the main clause.

The second common criterion of classification concerns the so-called grammatical function recoverability strategy, i.e., the indication of the modified noun in the RC. Four basic strategies are nonreduction, pronoun retention, relative pronouns, and gapping. Nonreduction involves a full NP which appears in the RC in its regular position and with the regular syntactic marking. This strategy is typical of internally headed RCs and exemplified in (8). In contrast, in externally-headed RCs the modified noun appears in a somehow reduced form.

Pronoun retention involves the use of a personal pronoun (sometimes called a resumptive pronoun in this function) inside the RC. The pronoun is coreferential with the head nominal and is syntactically marked to reflect the role of the head nominal in the RC, as in (9) from Gilbertese.

(9) [te mane are oro-ia] te aine
the man that hit-him the woman
'the man whom the woman hit'

This type sporadically occurs in non-standard English, e.g., *this is the road that I know where it leads*.

In the relative pronoun strategy the modified noun is represented in the RC by means of special pronouns, which are normally related to demonstratives and/or interrogatives. In (1) the relative pronoun *that* represents the external head *the dog*. This strategy is typical of most European languages but quite infrequent crosslinguistically. Unlike resumptive pronouns, which largely appear in the position the respective NP would occupy in the clause, relative pronouns have a distinct position of their own. There is a strong tendency for them to be located at the left periphery of the RC, although Keenan (1985: 151) points out that in a Bantu language Luganda they are prefixed to the clause-final verb. Relative pronouns are typically case-marked to encode the role of the head noun in the RC and may agree with the head noun in such features as number and gender. Case agreement – although very infrequent – is also attested in some languages.

The gapping strategy exemplified in (7) is the least explicit, as the head noun corresponds to a syntactic gap within the RC. This type is very widespread in the languages of the world. As there is no overt encoding of the role the head noun plays within the RC, the interpretation of the RC must rely on semantic and pragmatic clues, at least in languages in which the word order is relatively free. Example (7) can be understood unambiguously because the RC verb 'make' has the obligatory patient argument and it is not expressed within the RC itself. So the meaning of the syntactic gap can be recovered. But consider the following example from Khanty

(10) a:sʲe:-m joxt-əm xatl
father–1SG arrive-PART day
'the day when my father arrived'

In (10) the relativized noun is not an argument of the RC verb, so for the interpretation of the RC one must appeal to a general knowledge of the world: the most likely relation between the event of somebody's arriving and a day is temporal. In some cases the gapped RC may remain ambiguous, as in (11) from Imbabura Quechua.

(11) kan ʃamu-ʃka llajta-ka
you come-NOM town-TOP
'the town you are coming to/from'

The third parameter of classification is related to the syntactic status of the relativized noun within the RC. Keenan and Comrie (1977) have shown that a language can have several relativization strategies and their distribution is not random. They suggest the following now widely accepted hierarchy of grammatical functions, referred to as the Accessibility Hierarchy. The sign '>' here means 'is more accessible to relativization.'

(12) subject > direct object > indirect object > oblique argument > possessor > object of comparison

The first claim is that each relativization strategy covers a continuous segment on the hierarchy as a target of relativization. For example, there may be a language where one strategy is used to relativize subjects and direct objects, whereas another strategy is used to relativize the indirect object, oblique, possessor, and object of comparison. In fact, English is exactly such a language: the relative pronoun *who* serves to relativize subjects and direct objects, while for the relativization of lower positions on the hierarchy the relative pronoun has to combine with a preposition or take the oblique form *whose*. However, no language is predicted to use one strategy to relativize, for example, subjects and obliques, and another strategy to relativize direct objects and possessors. The second claim is that accessibility to relativization is progressively higher on the left periphery of the hierarchy. If a language can relativize a given position on the hierarchy, then it can relativize all positions to the left. All languages – or at least all languages that have RCs – have a strategy to relativize subjects. Many languages relativize only subjects and direct objects, for instance Kinyarwanda, whereas others, such as Tamil, relativize the three highest grammatical functions. The further one descends the hierarchy, the harder it is to relativize; the object of comparison being the least accessible function. Thus, in French and German all grammatical relations are relativizable, excluding the object of comparison.

Although subsequent work has demonstrated that hierarchy (12) may be refined in various ways (Maxwell, 1979; Lehmann, 1986), and that it seems to have exceptions (as also was acknowledged in the original proposal) in their essence Keenan and Comrie's conclusions remain largely unchallenged.

The three parameters of classification discussed above are not independent but exhibit systematic crosslinguistic correlations. First, the position of the RC with respect to the head correlates with accessibility to relativization. Adjoined RCs (and to a lesser extent internal RCs) typically allow relativization of the largest range of syntactic functions. Prenominal RCs are normally more constrained in their application than postnominal RCs: they relativize fewer grammatical functions and these are located on the left periphery of the hierarchy. Second, the strategy to represent the modified noun within the RC interacts with the position of the

clause. There is a significant quantitative difference between prenominal and postnominal RCs with respect to the pronominal representative of the modified noun within the clause. Postnominal RCs exhibit greater diversity and typically use either resumptive pronouns or relative pronouns. In fact, these strategies are mainly confined to postnominal RCs (Keenan, 1985: 151). In prenominal RCs pronouns representing the head noun are fairly rare, although not impossible, the most frequent strategy being gapping. In a similar manner, the recoverability strategy interacts with accessibility to relativization. When a language exhibits both pronoun retention and gapping, there is a great likelihood that the former is used lower down the hierarchy. Languages in which pronominal strategies are applied to subjects when gapping is applied to lower grammatical relations are not attested.

Various explanations have been provided for these correlations. Comrie (1989: 163) suggests a general functional principle that the more difficult a position is to relativize, the more explicit expression it needs for a successful recovery of information. The three reduced strategies of representing the head noun within the RCs can be ranked in the following way (cf. Song, 2001: 227).

(13) gapping > relative pronoun > pronoun retention

The sign '>' here means 'is less explicit than.' The lower grammatical relations are less accessible to relativization, so more information is required for the processing of the RC. Hierarchy in (13) predicts that pronoun retention is favored in this instance. In contrast, relativization of a higher grammatical relation need not be explicit and therefore allows gapping. An additional consideration is that pronoun retention and relative pronouns in prenominal RCs involve backward anaphora, i.e., an anaphoric pronoun preceding the coreferential NP. Backward anaphora is heavily constrained for processing reasons; therefore, pronominalization is dispreferred in prenominal RCs.

By contrast, Lehmann (1984, 1986) argues that the patterns described above are explainable by the notion of nominalization (desententialization). Nominalization is the reduction of sentential properties and acquisition of nominal properties that may characterise a dependent clause to a greater or lesser degree. It correlates inversely with the achievement on the Accessibility Hierarchy and with the representation of the head noun within the RC. The more strongly the RC is nominalized, the fewer grammatical functions it can relativize and the less likely it will allow the full representation of the head noun. Adjoined RCs are not syntactically embedded and show no signs of nominalization: they do not involve nonfinite verbs and do not exhibit word order patterns characteristic of subordinate clauses. This type is also the most explicit in that the relativized noun is not marked in any distinctive way to indicate its status as the head of the RC: it is represented by a full NP and takes the regular grammatical form. In contrast, prenominal RCs tend to be strongly nominalized: they make use of various nonfinite forms that show tense-aspect-mood and agreement reduction and exhibit some similarity to simple attributes, such as the participle in the Finnish example (7). The representation of the modified noun reduces to a gap. Such clauses are typically used to relativize higher grammatical relations, for example, the subject and the direct object in Finnish. Finally, postnominal and internal RCs tend to show intermediate degrees of nominalization across languages.

Some Theoretical Issues

The variety of RC types addressed in the previous section raises the following question: is there such a notion as a universal relative construction in Universal Grammar and if so, what are its properties? There are two competing approaches to the analysis of RCs in the theoretical literature on syntax, which differ according to their view on where in the structure the modified nominal originates and what its syntactic relation is to the RC.

In the more standard account, the RC is adjoined to the higher projection of the modified nominal (e.g., Jackendoff, 1977: 169ff.; Chomsky, 1977, 1981). For example, the RC in (1) corresponds to the following structure:

(14) $[_{DP}$ the $[_{NP}$ $[_{NP}$dog$_j$] $[_{CP}$ that you saw t_j]]]

The head of the relative is base-generated outside the RC and may be linked to the RC-internal relative phrase through some kind of interpretive mechanism (Chomsky, 1977; Safir, 1986). The RC is taken to be projected from a relative complementizer, which may be overt, as in (14), or covert. In the absence of a complementizer or a relative phrase the clause contains a null operator, i.e., an empty version of the overt relative pronoun. In theories that do not allow for null elements, the RC is projected from the highest verb (e.g., Sag, 1997).

The semantic difference between restrictive and nonrestrictive clauses is said to be reflected in the syntactic configuration. Because a restrictive RC is interpreted within the scope of the determiner and the c-command relation is usually thought to reflect the semantic scope, the restrictive RC is analysed as

adjoined to NP, as in (14). By contrast, nonrestrictive RCs are not interpreted within the scope of the determiner and are placed higher than restrictives, namely, in the determiner phrase (DP). However, there also are suggestions in the literature (e.g., Fabb, 1990; Grosu and Landman, 1998) that nonrestrictives do not form a constituent with the head and are not syntactically integrated into the host sentence. They are similar to parentheticals in that the relation between the head and the RC holds at the level of discourse and is usually signaled by intonational concord.

The position of the relative with respect to its external head is determined by the parametric variations in adjunction sites: left or right adjunction. An alternative proposal by Fukui and Takano (1998) is based on the assumption that only left-adjunction is allowed in the grammar. The ordering between a RC and its external head is due to the absence or presence of the determiner node D and the subsequent movement of N to D, which derives postnominal RCs. When D is not available and consequently N-to-D raising does not take place, the RC clause is head-final. These authors further attempt to provide a theoretical explanation for the typological observation that prenominal RCs disfavor relative pronouns: in such clauses a relative pronoun would not be c-commanded and properly bound by the external head.

The internally headed RCs are handled under adjunction analysis by means of various theory–internal mechanisms involving the external null head element at some point in the derivation. For example, Speas (1990) argues that in Navajo internally headed RCs the head is moved at Logical Form to the clause–external position, whereas Cole (1987) proposes that an internal RC is headed by a null pronominal coreferential with an internal head.

Under the alternative approach more recently developed in Kayne (1994), the RC is a syntactic complement of the determiner head of the DP rather than an adjunct. Given the binary branching hypothesis, the modified noun then cannot function as the complement of the determiner. Kayne proposes that it is generated internally to the RC from where it raises to the specifier of the respective CP, so (1) can be structurally represented as in (15).

(15) $[_{DP}$ the $[_{CP}$ $[_{DPj}$ dog] [that you saw t_j]]]

RCs with relative pronouns involve an additional raising of the modified nominal NP to the position of the specifier of the respective DP headed by a relative pronoun.

Evidence in support of the raising analysis mainly comes from two areas, the binding of variables and the interpretation of idioms. In (15) the modified nominal contains an anaphor that is bound by the embedded subject.

(16) the [[picture of himself]$_i$ that John saw t_i]

Because anaphors must be c-commanded by their antecedents, the well-formedness of (16) is expected if the raised head originates inside the RCs and is reconstructed in the trace position at some point of the derivation. Quantifier scope works in basically the same way. Thus, there is syntactic interaction between the subconstituents of the head nominal and the subconstituents of the RC. Furthermore, under the assumption that idioms form a constituent, idiom chunks must be interpreted internally to the RC.

(17) the [[headway]$_i$ that John made t_i]

In (17), the idiomatic reading of *headway* is only available if *headway* appears as a complement of the verb inside the RC.

The raising hypothesis appears fruitful in providing a unified approach to various relativization strategies not available under the adjunction analysis. On Kayne's suggestion, external and internal RCs are given essentially the same structure and differ only according to the overt/covert movement parameter: in internally headed RCs raising is covert. In a similar vein, the raising analysis assumes no major difference between restrictive relatives and free relatives, as free relatives are analysed as CP complements of a phonetically null determiner and are internally headed (cf. Groos and van Riemsdijk, 1981; Grosu, 1994). The distinction between restrictive and nonrestrictive relatives is reduced to different configurations at the level of the Logical Form. Bianchi (1999) also extends Kayne's raising proposal to account for correlative constructions.

However, raising analysis faces a number of further empirical questions (see its critique in Borsley, 1997, and a useful overview of relevant problems in Alexiadou *et al.,* 2000), so deciding between the two approaches is a difficult task. It is also conceivable that the variety of relative constructions cannot be captured by a uniform structure. Crosslinguistically RCs behave remarkably differently with respect to reconstruction effects and long-distance relations, which may argue for the existence of different strategies to derive relative constructions in Universal Grammar, whereas each specific language only chooses a subset of the available structures (cf. Bhatt, 2002; Sauerland, 2002).

RCs play an important role in more general theoretical discussions such as, for example, the nature of syntactic extractions and the locality of movement. Since the earliest days of generative grammar they provided evidence for the existence of the

so-called syntactic islands, i.e., structures that ban *wh*-movement. One of the islands formulated as the Complex NP Constraint prohibits extractions from clauses dominated by a NP, including RCs and NP-complements. This constraint, as well as other islands, follows from the more general Subjacency Condition introduced later in Chomsky (1981, 1986). It maintains that *wh*-movement operates in successive cycles and always lands in the closest Specifier of CP position. The movement cannot cross more than one blocking node such as DP or IP in English. For instance, in (18)

(18) *which country$_i$ did [$_{IP}$ he write [$_{DP}$ a book [$_{CP}$ which$_j$ [$_{IP}$ t$_j$ was about t_i]]]]

the movement of *which country* crosses at least a DP and an IP and so violates Subjacency. These insights were further developed in much subsequent work which relies on the basic idea that extractions must be local, cyclic, and sensitive to syntactic islands.

Another area where the analysis of RCs has proved to be of a more general importance is grammatical relations. Keenan and Comrie's Accessibility Hierarchy provides strong support both for the notion of subject and its privileged status in grammar as the highest point on the hierarchy. Evidence from the facts of relativization suggests that the notion of subject is applicable to languages in which the subject shows no strong association with particular semantic role(s). Languages such as Malagasy have heavy constraints on relativization: only subjects can be relativized. Relativization of oblique semantic relations is achieved by means of a rich voicing system, which serves to promote the respective argument to subject, so that relativization can apply. The existence of subject in languages with ergative alignments has been a matter of some controversy, but the relativization data rather shows that the notion of subject is associated with the absolutive, which corresponds to the single argument of intransitive verbs or the secondary argument of transitive verbs. This situation is attested in Dyirbal, so Keenan and Comrie (1977: 84–85) argue that in this language the subject relation encompasses absolutive arguments to the exclusion of the ergative primary arguments of transitive verbs. The latter can be relativized only after the original transitive clause is detransitivized via antipassivization.

Because in languages such as Kinyarwanda only subjects and direct objects are relativizable, Accessibility Hierarchy provides further evidence for the existence of lower grammatical relations. However, there are alternative suggestions concerning the nature of relativization. According to some authors, the most important condition is that the speakers must be able to infer a plausible relation between the head and the modifying clause (Comrie, 1998, 1999). In the following example from colloquial English

(19) a cake where you don't gain weight

no syntactic relation holds between the head noun and the RC. In other languages, for example Japanese or Basque, such RCs are regular, and it is not immediately obvious whether the extraction analysis would necessarily work for them. Because structural reasons do not seem to be sufficient to formulate relativization constraints, Matsumoto (1997) proposes an analysis of Japanese RCs based on the semantic frame that the predicate suggests. A similar problem is presented by languages where relativization of genitives/possessors is sensitive to semantico-pragmatic appropriateness, e.g., Chamorro and Tsez. In sum, it remains to be seen to what extent relativization patterns are explainable by purely syntactic constraints, formulated either in terms of grammatical relations or structural configurations, or whether they are more pragmatic in nature.

Introduction

This article focuses on relative clauses in unplanned spoken language. Unplanned speech is produced by speakers of standard and nonstandard varieties alike, and most of the relative clause types examined below are found in both standard and nonstandard English. In fact it may be impossible to establish a boundary between spoken standard and spoken nonstandard in English or any other language (see Comrie, 1999). The relative clause constructions that do belong to geographical nonstandard varieties will be clearly signaled.

Examples (1a–d) give very common types of relative clause in unplanned spoken English:

(1a) the book I read
(1b) the book I found the picture in
(1c) the book that I read
(1d) the book that I found the picture in

The relative clauses *I read* and *I found the picture in* are next to the head noun *book*, or linked to it by *that*. (1a, b) are contact relative clauses. Examples (2a–d) give the corresponding wh- relative clauses:

(2a) the book which I read
(2b) the book in which I found the picture
(2c) the book which I found the picture in

Which links the relative clause to the head noun. Prepositions either precede the wh- word, as in (2b), or are at the end of the clause, as in (2c). If the head noun is human, as in *the girl who helped me*, the wh-word is 'who.' In formal writing 'whom' is the form used if the wh- word is the object of a verb or preposition in the relative clause, e.g., *the girl whom I met*, *the girl to whom I lent that book*; 'whose' is used if the wh- word refers to a possessor: *the girl whose car I borrowed*.

(1a–d) are typical of unplanned speech; the construction in (2b) is almost absent from unplanned speech. Relative clauses with 'whom' and 'whose' are likewise absent. (2a, c) do occur in unplanned

Introduction

This article focuses on relative clauses in unplanned spoken language. Unplanned speech is produced by speakers of standard and nonstandard varieties alike, and most of the relative clause types examined below are found in both standard and nonstandard English. In fact it may be impossible to establish a boundary between spoken standard and spoken nonstandard in English or any other language (see Comrie, 1999). The relative clause constructions that do belong to geographical nonstandard varieties will be clearly signaled.

Examples (1a–d) give very common types of relative clause in unplanned spoken English:

(1a) the book I read
(1b) the book I found the picture in
(1c) the book that I read
(1d) the book that I found the picture in

The relative clauses *I read* and *I found the picture in* are next to the head noun *book*, or linked to it by *that*. (1a, b) are contact relative clauses. Examples (2a–d) give the corresponding wh- relative clauses:

(2a) the book which I read
(2b) the book in which I found the picture
(2c) the book which I found the picture in

Which links the relative clause to the head noun. Prepositions either precede the wh- word, as in (2b), or are at the end of the clause, as in (2c). If the head noun is human, as in *the girl who helped me*, the wh-word is 'who.' In formal writing 'whom' is the form used if the wh- word is the object of a verb or preposition in the relative clause, e.g., *the girl whom I met*, *the girl to whom I lent that book*; 'whose' is used if the wh- word refers to a possessor: *the girl whose car I borrowed*.

(1a–d) are typical of unplanned speech; the construction in (2b) is almost absent from unplanned speech. Relative clauses with 'whom' and 'whose' are likewise absent. (2a, c) do occur in unplanned

speech, but rarely. Biber *et al.* (1999: 610) found that contact relative clauses were proportionately most common in conversation. Miller and Weinert (1998) found no relative clauses introduced by 'whom' or 'whose'; Biber *et al.* found a miniscule number of relative clauses with 'whom' and an even smaller number with 'whose.'

(1a–d) and (2a–c) exemplify integrated relative clause syntax. In (2) the wh- word overtly links the relative clauses to their head nouns; 'who,' 'whom,' and 'whose' signal the role of the wh- word in the relative clause. In (1c, d) *that* links the relative clauses to the nouns they modify but there is a second, covert, link: there is a gap in each relative clause which can be filled in with invented examples such as *the book I read which* and *the book I found the picture in which*. (1a, b) also have gaps; compare *the book I read it*.

Relative Clauses with Resumptive Pronouns

The above invented examples parallel a frequent construction in unplanned spoken English.

(3a) I'm one of these people that **I** don't like surprises [conversation]
(3b) it's something that I keep returning to **it** [radio discussion]

(3a, b) contain resumptive pronouns, shown in bold. Resumptive pronouns occur in simple relative clauses; in (3a) *I* is even the grammatical subject. Some analysts have suggested that resumptive pronouns offer a way of solving planning difficulties with syntax. This is true but it is not their *raison d'être*, as (3a, b) show.

Instead of 'whose,' unplanned speech typically has the ordinary possessive pronouns 'his,' 'her,' 'their,' etc., as in (4):

(4a) if you've got some eggs you're not sure about **their** age here's a useful test [cookery program on New Zealand television]
(4b) the man that **his** wife died [cited in Murray, 1873]

In formal writing (4a) would be *if you've got some eggs about whose age you're not sure here's a useful test*. This version is difficult to process; speakers have to construct a relative clause beginning with a complex prepositional phrase, *about whose age*, and listeners have to interpret it. (4a) introduces the eggs – *if you've got some eggs*; the next chunk has the word order of ordinary main clauses – *you're not sure about their age*. The listener merely has to pick up the reference of *their*. The shadow pronoun construction enables speakers to avoid complex relative clauses in which the relative pronoun is an oblique object or a possessive.

Relative Clauses with Subject Gaps

Let us return to (1a) and the missing object – see the invented example *the book I found the picture in which*. Where the missing piece is the subject of the relative clause, the construction is described as unacceptable: **the student came to see me yesterday was worried about the exam*. However, a number of spoken constructions do allow a subject gap, as in (5):

(5a) we had this French girl came to stay [conversation]
(5b) my friend's got a brother used to be in the school [conversation]
(5c) there's some of us look on the absence of planes with utter joy, old boy [Giles cartoon, London *Daily Express*, July 30, 1978]

(5a–c) were used to assert the existence of an entity – *this French girl*, *a brother*, *some of us*, but nonpresentational examples occur such as *the man lives there is a nice chap*, in which *lives there* is a relative clause with the subject missing. This example seems on the borderline between standard and nonstandard and it is not yet known how frequently the construction occurs or whether it is even counted in computer scans of digital corpora.

Relative Clauses Weakly Linked to Their Antecedent

Gaps and items such as 'that,' 'which,' 'who,' 'what,' and 'as' integrate the relative clause and the noun it modifies into a tightly organized noun phrase. In contrast, many examples of relative clauses in unplanned speech are very loosely integrated with the head noun. Examples are in (6).

(6a) you have a little keypad down here **which** you can use your mouse to click on the keys [university finance officer at seminar]
(6b) the tourists are sent to hostels **which** many of them are fire hazards [radio]
(6c) there are parkas **that** you can take the lining out and wear it on its own [quoted in the *New Zealand Herald*, October 25, 2003]

In (6a) the clause *you can use your mouse to click on the keys* provides information about the keyboard but, as will be shown below, there is doubt as to whether *which* is a relative pronoun. The clause *you can use* . . . is a complete clause; there are no gaps. (6b) has the same properties. In (6c) the clause *you can take the lining out and wear it on its own* provides information about a certain type of parka and *that* can be analyzed as a subordinating conjunction.

Examples such as (7) make it difficult to decide on the analysis of (6a, b).

(7) you can leave at Christmas if your birthday's in December to February which I think is wrong like my birthday's March and I have to stay on to May **which** when I'm 16 in March I could be looking for a job

When I'm 16 in March . . . does not modify a noun and is not a relative clause. *Which* in bold connects two pieces of discourse, the piece dealing with dates for leaving school and the piece about looking for a job. (6a) too can be seen as two pieces of discourse linked by *which*; that is, *you can use your mouse to click on the keys* is not a relative clause, and similarly for (6b). It is possible that in (6c) *that* is not a subordinate conjunction but a discourse linker. (The change from pronoun to conjunction is well attested in Indo-European.)

In contrast to the above examples, formal written language offers far more complex relative clauses. The examples in (8) illustrate the point.

(8a) the hospital admitted several patients that month, for all of whom chemotherapy was the appropriate treatment

(8b) we read several government reports the gold lettering on the covers of which was admired by all the officials

Finally, we refer to infinitival relative clauses. These can be simple, e.g., *she is not a person to rely on*, or complex, e.g., *she is not a person on whom to rely*. The type *on whom to rely* is very rare in unplanned speech. English has reduced relative clauses, as in *the book lying on the table* or *the book written by my colleague*. This construction too is rare in unplanned speech but frequent in writing.

Relative Clauses in Other Languages

The English data have parallels in many other languages. The resumptive pronoun structure is widespread, as in the Italian example below – see Fiorentino (1999). (Resumptive pronoun in bold.)

(9)

questa	benedetta	riforma	che	se	**ne**
this	blessed	reform	that	self	of-it
sta	parlando	da	secoli		
stands	speaking	from	centuries		

'this blessed reform that people have been speaking about for centuries'

Unplanned spoken Italian and French offer examples of unintegrated relative clauses like those in (6). In (10), from Fiorentino (1999), the conjunction *che* links the relative clause to *mondo* and the preposition *sopra* governs neither a relative nor a resumptive pronoun.

(10)

La	terra	non	il	mondo	è	quello
the	region	not	the	world	is	that-thing
che	noi	teniamo	i	piedi	sopra	
that	we	hold	the	feet	on	

'the local region and not the world is what we have our feet on'

Example (11) shows a spoken Russian construction which is not found in written Russian. The first clause, *kotorye mal'chiki lomaiut*, sets up the referent and the second clause, *on vsekh zabiraet*, provides extra information about the referent.

(11)

kotorye	mal'chiki	lomaiut	on	vsekh	zabiraet
which	boys	break	he	all	catches

'he catches all the boys who vandalize things' (Lapteva, 1976)

Spoken relative clause constructions ease the production and interpretation of utterances in real time. Resumptive pronouns make possible the same word order in relative clauses as in main clauses; one clause identifies the referent and another clause supplies extra information as in (11). Complex constructions occur in written language; speakers have minimal time to plan, while writers have time to plan and edit.

The spoken relative clause structures are not new; Fiorentino (1999) traces the Romance constructions to Late Latin. The construction probably predates Late Latin but took time to appear in written texts. One hypothesis is that the structure arose out of discourse, as exemplified in the German example in (12):

(12)

und	jetzt	hat	er	ein	Mädchen
and	now	has	he	a	girl
die	ist	alles	andere	als	schön
she	is	all	else	than	pretty

'and now he has a girl who is anything but pretty'

The 'relative clause' is introduced by *die*, which functions as definite article or personal pronoun. Here it is a personal pronoun pointing at a female person. Were it a relative pronoun with *Mädchen* as its antecedent, the required form would be 'das.' In subordinate clauses in German the finite verb is at the end of the clause; here it is in second position – *ist*. That is, (12) consists of two main clauses linked by the fact that they are juxtaposed and that *die* picks up the referent of *ein Mädchen*.

Restrictive and Nonrestrictive Relative Clauses in Unplanned Speech

Traditionally, a distinction has been drawn between restrictive relative clauses, which help to identify a referent, and nonrestrictive relative clauses, which merely add extra information, as in *the book, which*

I didn't buy after all, turned out to be useless. Non-restrictive relative clauses are rare in unplanned speech and recent work suggests that speakers actually use relative clauses for three purposes, to describe, confirm, or identify referents (see Weinert, 2004).

To sum up, spoken relative clauses are central in research on spoken and written language, on the distinction between the grammatical resources of languages and their users, and on typology.

Relativism

S Chapman, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

The philosophical term 'relativism' covers any belief that some type of judgment is necessarily dependent on the particular point of view from which it is made. Moral relativism is the view that judgments of right and wrong are always relative to the value system of an individual making the judgment. In the work of Franz Boas, this led to cultural relativism – the argument that moral judgments vary between different social groups, and that it is not appropriate to claim that any one such group has a 'better' moral code than any other. Truth-relativism claims that statements are only ever true or false from the point of view of some way of understanding the world, relative to an individual, a society, or even a whole species.

Proponents of relativism argue that it acknowledges the fact that our judgments are necessarily influenced by our system of perception or by social conditioning. Opponents often cite what they see as unacceptable consequences. Relativism in ethics leads to moral nihilism, or the claim that there can be no objective moral absolutes and, therefore, that it is impossible to deprecate any form of behavior if it is acceptable to the individual performing it. Truth-relativism can be seen as having unacceptable consequences for logic. If A believes that 'p is true' and B believes that 'p is false,' there can be no contradiction between the beliefs of A and B, since each is true, relative to the individual.

Relativism had a profound effect on the study of language in the 20th century. Moral relativism is apparent in the claim that statements of right and wrong can only ever be contingently, never absolutely, true. Even more forceful is the verificationist claim that all the statements of ethics are strictly meaningless, because they cannot be objectively verified. For instance, A. J. Ayer argued that a sentence such as 'stealing is wrong' fails to express any proposition; it merely reports a personal, emotional response to stealing. Most significantly, much of structural linguistics draws on relativist arguments. Saussure argued that language is a necessary precursor to thought, or to a full understanding of reality. This leads to the claims of linguistic relativism, or relativity, that the particular language an individual learns determines that individual's worldview. Coupled with the structuralist belief that human languages share a level of complexity but otherwise differ radically from each other, linguistic relativity leads to the belief that the worldviews implicit in different languages can vary without limit, and therefore that the way speakers of one language understand the world may be radically different from the way speakers of another language do. This view found fullest expression in the claims of Benjamin Lee Whorf that different languages provide speakers with different 'isolates' of meaning, and that these determine how speakers understand reality, or what is 'true' for them. Although the more extreme claims of linguistic relativity are generally now seen as untenable, this idea continues to have a strong

Relevance Theory

F Yus, University of Alicante, Alicante, Spain

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (henceforth RT), a cognitive theory of human communication developed by D. Sperber and D. Wilson, was fully described in their 1986 book (Sperber and Wilson, 1986, 2nd edn., 1995), but it really emerged in the late 1970s and early 1980s as a cognition-centered alternative to Grice's cooperation-ruled explanation of human communication (see Wilson and Sperber, 1981). Since then, it has been a highly influential theory in pragmatics producing a good number of studies backing it up, criticizing it, or applying it to different pragmatic research areas (see Yus, 1998; Wilson and Sperber, 2002a; and RT Bibliography).

The main assumption of the theory is that human beings are endowed with a biologically rooted ability to maximize the relevance of incoming stimuli (including linguistic utterances and other communicative behavior). Relevance is not only a typical property of external stimuli (e.g., utterances), but also of internal representations and thoughts, all of which may become inputs for cognitive processing. The pursuit of relevance is a typical aspect of the mental activity of human beings, always geared to obtaining the highest reward from the stimuli that they process. This biological endowment is the result of the evolution of the architecture and complexity of the human mind and part of a general human ability to meta-represent one's and other people's thoughts and intentions: "As a result of constant selection pressure towards increasing efficiency, the human cognitive system has developed in such a way that our perceptual mechanisms tend automatically to pick out potentially relevant stimuli, our memory retrieval mechanisms tend automatically to activate potentially relevant assumptions, and our inferential mechanisms tend spontaneously to process them in the most productive way" (Wilson and Sperber, 2002a: 254). Together with another uniquely human cognitive endowment, the ability to metarepresent one's and other people's thoughts and intentions, this tendency to maximize relevance allows us to predict what information is likely to be relevant to other people and what interpretive steps might be involved in its processing, and therefore allows for the manipulation of other people's thoughts.

Basic Claims

Four statements can summarize this theory (Wilson, 1994: 44): (a) the decoded meaning of the sentence is compatible with a number of different interpretations in the same context; (b) these interpretations are graded in terms of accessibility; (c) hearers rely on a powerful criterion when selecting the most appropriate interpretation; and (d) this criterion makes it possible to select one interpretation among the range of possible interpretations, to the extent that when a first interpretation is considered a candidate matching the intended interpretation, the hearer will stop at this point.

These statements can be broken down into a number of basic claims, as summarized below.

Code versus Inference

Unlike the so-called **code model** of communication, according to which messages are simply coded and decoded, Sperber and Wilson favor an **inferential model** in which decoding plays a minor role compared with the inferential activity of the interpreter. Within this approach, the decoding of utterances underdetermines their interpretation and serves rather as a piece of evidence about the speaker's meaning. Verbal communication does involve the use of a code (i.e., the grammar of the language), but inference plays a major role in turning the schematic coded input into fully propositional interpretations.

influence on discussions of language and point of view.

Relevance Theory

F Yus, University of Alicante, Alicante, Spain

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (henceforth RT), a cognitive theory of human communication developed by D. Sperber and D. Wilson, was fully described in their 1986 book (Sperber and Wilson, 1986, 2nd edn., 1995), but it really emerged in the late 1970s and early 1980s as a cognition-centered alternative to Grice's cooperation-ruled explanation of human communication (see Wilson and Sperber, 1981). Since then, it has been a highly influential theory in pragmatics producing a good number of studies backing it up, criticizing it, or applying it to different pragmatic research areas (see Yus, 1998; Wilson and Sperber, 2002a; and RT Bibliography).

The main assumption of the theory is that human beings are endowed with a biologically rooted ability to maximize the relevance of incoming stimuli (including linguistic utterances and other communicative behavior). Relevance is not only a typical property of external stimuli (e.g., utterances), but also of internal representations and thoughts, all of which may become inputs for cognitive processing. The pursuit of relevance is a typical aspect of the mental activity of human beings, always geared to obtaining the highest reward from the stimuli that they process. This biological endowment is the result of the evolution of the architecture and complexity of the human mind and part of a general human ability to meta-represent one's and other people's thoughts and intentions: "As a result of constant selection pressure towards increasing efficiency, the human cognitive system has developed in such a way that our perceptual mechanisms tend automatically to pick out potentially relevant stimuli, our memory retrieval mechanisms tend automatically to activate potentially relevant assumptions, and our inferential mechanisms tend spontaneously to process them in the most productive way" (Wilson and Sperber, 2002a: 254). Together with another uniquely human cognitive endowment, the ability to metarepresent one's and other people's thoughts and intentions, this tendency to maximize relevance allows us to predict what information is likely to be relevant to other people and what interpretive steps might be involved in its processing, and therefore allows for the manipulation of other people's thoughts.

Basic Claims

Four statements can summarize this theory (Wilson, 1994: 44): (a) the decoded meaning of the sentence is compatible with a number of different interpretations in the same context; (b) these interpretations are graded in terms of accessibility; (c) hearers rely on a powerful criterion when selecting the most appropriate interpretation; and (d) this criterion makes it possible to select one interpretation among the range of possible interpretations, to the extent that when a first interpretation is considered a candidate matching the intended interpretation, the hearer will stop at this point.

These statements can be broken down into a number of basic claims, as summarized below.

Code versus Inference

Unlike the so-called **code model** of communication, according to which messages are simply coded and decoded, Sperber and Wilson favor an **inferential model** in which decoding plays a minor role compared with the inferential activity of the interpreter. Within this approach, the decoding of utterances underdetermines their interpretation and serves rather as a piece of evidence about the speaker's meaning. Verbal communication does involve the use of a code (i.e., the grammar of the language), but inference plays a major role in turning the schematic coded input into fully propositional interpretations.

One of the most interesting contributions of RT is, precisely, the claim that there is a wide gap between the (coded) sentence meaning and the (inferred) speaker's meaning, which has to be filled inferentially. Comprehension starts at the context-free identification of the utterance's logical form, which is then enriched to yield explicit information (**explicatures**) and/or implicit information (**implicatures**) (*see* **Implicature**).

A Post-Gricean Theory

Sperber and Wilson acknowledge the filiation of RT from Grice's view of communication, but there are several aspects in which they depart from Grice. This is the reason why we can call RT a post-Gricean theory (*see* **Neo-Gricean Pragmatics**), a theory that takes the Gricean approach to communication as a mere starting point, as opposed to neo-Gricean theories which stay much closer to Grice's cooperative principle and its maxims (*see* **Grice, Herbert Paul (1913–1988); Cooperative Principle; Maxims and Flouting**) Several points deserve explanation:

1. One of the major contributions by Grice was to underline the role that intentions (roughly defined as mental representations of a desired state of affairs) play in human communication. His emphasis on the expression and recognition of intentions laid the foundations of the inferential model of communication. Crucially to Grice, the hearer explains the speaker's communicative behavior by identifying the underlying intention, a typically human form of mind-reading activity. However, Sperber and Wilson do not agree with the complex schema of human reasoning that Grice proposed for the derivation of implicatures.

   Sperber and Wilson also point out that Grice's emphasis on the role of intentions corroborates the fact that communication can exist without the need for a code. All that the communicator has to do to communicate a thought is to get the addressee to recognize his/her intention to convey it.

   Sperber and Wilson distinguish two levels of intention: **informative** (an intention to inform the hearer of something) and **communicative** (the intention to inform the addressee of that informative intention). In inferential communication, the identification of the informative intention is done through the identification of the communicative intention, the process being activated by verbal ostensive communication, in which it is clear to both speaker and hearer (**mutually manifest** in Sperber and Wilson's terminology) that the speaker has the (metarepresentational) intention to communicate something. Unlike other forms of information transmission, 'ostensive inferential communication' involves both types of intention, and is achieved by ostensively providing an addressee with evidence that helps him/her infer the speaker's meaning.
2. RT explains the hearer's inference of the (intended) speaker's meaning from the coded sentence meaning by resorting to another central claim suggested by Grice: that ostensively communicated utterances automatically generate expectations that activate the hearer's search for the speaker's meaning. But whereas Grice explained these expectations in terms of the assumption by hearers that speakers were observing the cooperative principle and its maxims, within RT these expectations are explained in cognitive terms (basically proposing the existence of a Cognitive Principle of Relevance), without reliance on a cooperative principle.
3. For Sperber and Wilson, no maxims, in the Gricean sense, are required for the explanation of communication. This is especially evident in the case of the Maxim of Quality (roughly, 'tell the truth'), which Grice proposed for the explanation of figurative language and irony. Sperber and Wilson have shown that people are normally 'loose' when they speak and only on very specific occasions do they intend their utterances to be regarded as literally true. In addition, Sperber and Wilson propose that all uses of language, whether loose (metaphor, hyperbole, etc.) literal can be addressed with a single explanatory framework based on general expectations of relevance.

Two Principles of Relevance

Initially, Sperber and Wilson proposed one Principle of Relevance to account for the fact that an act of 'ostension' carries a guarantee of its eventual relevance, but in the Postface to the second edition of their book (Sperber and Wilson, 1995: 260ff.), they propose that we can distinguish a broad **cognitive principle of relevance**: "human cognition tends to be geared to the maximisation of relevance," as well as a narrower (**communicative principle of relevance**: "every act of ostensive communication communicates a presumption of its own optimal relevance"; 1986: 158), the latter being the main focus of analysis within pragmatics. But the former is important, too, because it stresses the fact that we are biologically geared toward processing the most relevant inputs available. In addition, it is this evolved disposition that allows for the prediction of the mental states of others, which is crucial in human communication.

The communicative principle involves a definition of optimal relevance comprising two parts: (a) The ostensive stimulus is relevant enough for it to be worth the addressee's effort to process it; and (b) The

ostensive stimulus is the most relevant one compatible with the communicator's abilities and preferences (Sperber and Wilson, 1995: 267, 270). As Wilson and Sperber (2002a: 257–258) correctly point out, communicators "cannot be expected to go against their own interests and preferences in producing an utterance. There may be relevant information that they are unable or unwilling to provide, and ostensive stimuli that would convey their intentions more economically, but that they are unwilling to produce, or unable to think of at the time." All this is covered by clause (b) of the definition of optimal relevance, which states that the ostensive stimulus is the most relevant one "that the communicator is WILLING AND ABLE to produce" (Sperber and Wilson, 1995: 258).

Assessing Relevance: Cognitive Effects versus Processing Effort

Unlike what is the case in 'static' pragmatics, which foregrounds the importance of context but somehow takes it for granted or is merely interested in dissecting, as it were, its elements, Sperber and Wilson's theory views the context as a dynamic, mental entity made up of a subset of the person's assumptions about the world; it is this subset that is accessed in the search for relevance. Often several extensions of context are required to arrive at an optimally relevant interpretation, but as soon as one interpretation is found to be satisfactory, interpretation stops and no other interpretive hypotheses are considered: "When a hearer following the path of least effort finds an interpretation which satisfies his expectations of relevance, in the absence of contrary evidence, this is the best possible interpretive hypothesis" (Wilson and Sperber, 2002b: 605).

The aforementioned Communicative Principle of Relevance predicts a basic procedure for hearers when hypothesizing about contextual extensions required for the interpretation of a verbal stimulus: to consider interpretive hypotheses in order of accessibility (following a path of least effort) and to stop when they arrive at an interpretation which satisfies the expectations of relevance raised by the stimulus itself. Relevance, then, is a matter of balance between the interest that the utterance might provide (in terms of so-called 'positive cognitive effects') and the mental effort that obtaining this interest demands.

Relevance is a characteristic of an input to the human cognitive processes which, when processed in a certain context, yields positive cognitive effects. Because there are too many possible stimuli to which we can pay attention, our cognitive architecture is designed to allocate our processing effort in such a way that benefit is maximized. Hence, relevance has to do with the improvement of the person's knowledge; this can be achieved either by adding new information, by revising existing assumptions, or by yielding new conclusions resulting from the combination of old and new information (in this case **contextual implications** are generated) (*see* **Context, Communicative**).

The definition of relevance of an input to an individual involves two clauses: "(a) everything else being equal, the greater the positive cognitive effects achieved in an individual by processing an input at a given time, the greater the relevance of the input to that individual at that time; and (b) everything else being equal, the smaller the processing effort expended by the individual in achieving those effects, the greater the relevance of the input to that individual at that time" (Wilson and Sperber, 2002b: 602).

Current Issues and Open Debates

The Explicit/Implicit Distinction

One of the key differences between Grice's model and Sperber and Wilson's lies in the demarcation of explicit and implicit communication. For Grice, **what is said** involved little inference, mainly reduced to disambiguation and reference assignment, while all the inferential load was laid upon the derivation of implicatures, the latter being obtained **after** an interpretion reduced to the literal meaning has been found inappropriate, in a so-called **dual-stage processing**. Sperber and Wilson reject this view and favor a more adequate, **mutual parallel adjustment** of explicit content – explicatures – and implicit import – implicatures – during interpretation, and with no preconceived sequential arrangement.

Within RT, explicitly communicated information not only demands as much contextualization as do implicatures, but also covers aspects of communicated meaning which Grice included in the term implicature (e.g., the so-called **generalized conversational implicatures**, most of which are now pictured as explicit information, see Levinson, 2000; Carston, 2002).

In addition to implicatures, Sperber and Wilson propose two types of explicitly communicated information: the basic-level **explicature**, and the **higher-level explicature**. The latter also includes the speaker's attitude (*to regret that* . . . *to be happy that* . . . etc.) or a higher-order speech-act schema (*to be asking that* . . . *to be ordering that* . . . etc.). Both explicatures and implicatures allow for degrees (i.e., strong and weak explicatures/implicatures), depending on the addressee's responsibility for their derivation and the amount of mental processing required.

Other notions used by other authors in the definition of explicit information, for instance **literal meaning** or **what is said,** are put into question by Sperber

and Wilson, because these do not play any useful role in the study of verbal comprehension: "even when a literal meaning is available, it is not automatically the preferred interpretation of an utterance. In fact, literalness plays no role in our account of language comprehension, and nor does the notion of what is said" (Wilson and Sperber, 2002b: 586). This is because, among other reasons, hearers commonly derive loose interpretations rather than purely literal ones: "hearers have no objection to strictly false approximations as long as the conclusions they bother to derive from them are true. In fact, they might prefer the shorter approximations to their longer-winded but strictly true counterparts for reasons of economy of effort" (Wilson and Sperber, 2002b: 598).

Whereas Bach (1994) has proposed a third term, **impliciture**, half-way between explicatures and implicatures, other authors, such as Vicente (2002), reject this blurring of the explicit/implicit dichotomy. The term 'impliciture' covers several cases which would fit into Sperber and Wilson's notion of explicature, basically being completions of the semantic representation of the sentence (e.g., 'The table is too wide' [to go through the door]) and nonliteral uses of sentences in which no constituent is being used nonliterally, what Bach calls **standardized nonliterality** (e.g., (said to a person who has cut himself) 'You are not going to die' [from this cut]).

Conceptual and Procedural Encoding

One of the most interesting lines of research within relevance theory is the one that differentiates between **conceptual meaning** and **procedural meaning**. Wilson and Sperber (1993: 10) summarize this dichotomy as follows: "inferential comprehension involves the construction and manipulation of conceptual representations; linguistic decoding feeds inferential comprehension; linguistic constructions might therefore be expected to encode two basic types of information: concepts or conceptual representations on the one hand, and procedures for manipulating them on the other."

Most words encode concepts, but some words give instructions as to how conceptual representations are to be manipulated and hence encode procedural meaning. Blakemore and her followers applied the notion to connectives (Blakemore, 1987) and discourse markers (Blakemore, 2002), which constrain the inferential phase by indicating the kind of inferential process that the hearer should go through (hence reducing the eventual overall effort) in the subsequent stretch of discourse. In recent research, the list of procedural items has been extended to cover nonverbal elements such as intonation (*see* **Meaning, Procedural and Conceptual**).

Ad hoc Concept Formation

The notion of *ad hoc* concept construction is one of the latest developments of relevance theory in the area of figurative language (especially metaphors), which has also been extended to the analysis of how concepts in general are processed (cf. Carston, 2002; Pilkington, 2000).

The traditional relevance–theoretic account of figurative language relies on the assumption that there is an interpretive resemblance between the coded concept and the intended thought. And we can say the same about the whole utterance whose propositional form resembles the propositional form of the communicator's thought (Pilkington, 2000: 90). From this viewpoint, the interpretive resemblance between, for instance, a coded metaphor and the thought which it resembles would lead to the hearer's derivation of stronger/weaker implicatures.

Within an alternative account of utterance interpretation, it is claimed that the metaphor provides a new *ad hoc* concept for the proposition expressed by the utterance (instead of favoring the derivation of implicatures) (*see* **Metaphor: Psychological Aspects**). Encyclopedic entries would be explored in such a way that an increase in the *salience* of a number of assumptions is created, providing an encyclopedic entry for the new concept (Pilkington, 2000: 95-96; for 'salience,' see Giora, 2002). They are *ad hoc* "because they are not linguistically given, but are constructed online in response to specific expectations of relevance raised in specific contexts. There is a difference then between *ad hoc* concepts, accessed by a spontaneous process of pragmatic inference, and lexicalized concepts, which are context-invariant" (Carston, 2002: 322).

Mutual Knowledge versus Mutual Manifestness

Sperber and Wilson reject the traditional notion of mutual knowledge because it generates an endless recursion (A knows that p, B knows that A knows that p, A knows that B knows that A knows that p, and so on). Instead, they propose the notion of **mutual manifestness** (see Sperber and Wilson, 1990). What is 'manifest' is what one is capable of inferring or capable of perceiving, even if one hasn't done so yet. The sum of all the manifest assumptions is the person's **cognitive environment**. A set of assumptions manifest to several individuals constitutes their shared cognitive environment. When it is manifest to all the people sharing a cognitive environment that they share it, then, this is a **mutual cognitive environment**, made up of mutually manifest assumptions. Communication is a matter of making certain

assumptions mutually manifest to both speaker and hearer.

Several authors have criticized the notion of mutual manifestness. For example, Mey and Talbot (1988) point out that what Sperber and Wilson do is to send mutual knowledge out at the front door and then let it in at the back, disguised as 'mutually manifest assumptions.' For these authors, cognitive environments are not distinguishable from mutual knowledge; thus, Sperber and Wilson appear to be using the same concept that they want to abandon. To my knowledge, neither Sperber and Wilson nor their critics have been persuaded to abandon their differing claims on mutuality.

Communicated and Noncommunicated Acts

One of the most underdeveloped areas within relevance–theoretic research is the relationship between RT and speech acts. In short, Sperber and Wilson (1986: 244–246) distinguish between communicated and noncommunicated acts. The former depend on the addressee's perception that a certain speech act has been performed (e.g., admitting, promising, thanking), while in non-communicated acts, communication does not depend on the identification of a particular speech act (e.g., predicting, warning, suggesting). In this case, successful communication lies in the hearer's recovery of adequate cognitive effects from the utterance with the aid of context and in the recovery of the speaker's intentions.

In a recent paper, Nicolle (2000) has argued against the existence of noncommunicated speech acts in the RT sense. Examples of noncommunicated acts (such as the act of warning in "The path is slippery here") are reconsidered by Nicolle in social terms, and their influence on the interlocutors' social environments implies that they also have to be communicated: "the recovery of information relating to social relations is an essential element of the comprehension process. When the recovery of such information depends on the identification of a particular speech act, that speech act is by definition a communicated act" (Nicolle, 2000: 239).

Irony and the Notion of Echo

In Wilson and Sperber (1992), the authors conceptualize irony in **interpretive** terms. An ironic utterance is an interpretation of another thought, utterance, or assumption that it resembles and which the speaker attributes to a different speaker or to himself/herself at another time. Ironic utterances are echoic, that is, they simultaneously refer to an attributed thought – or utterance, or assumption – and express an attitude to it. More specifically, the speaker's attitude toward what is echoed has to be dissociative. This dissociation may apply to either the proposition expressed by the utterance, or to some effect that is generated by that utterance.

Several authors have commented upon this proposal. For instance, in some of the papers collected in Carston and Uchida (1998) it is claimed that irony can be nonechoic. In their reply, Sperber and Wilson (1998) maintain that although most utterances cannot be understood as echoic (i.e., there is no accessible representation that they might be taken to echo), an utterance has to be echoic to be interpreted as ironical (*see* **Irony**).

Modularity

Initially, Sperber and Wilson adopted the view of the mental architecture of the mind proposed by Jerry Fodor in the early 1980s: several modules feeding a central processor with specific information.

Modules are evolved, special-purpose mental mechanisms, typically automatic, informationally encapsulated, and domain-specific. For instance, the language module is only (and automatically) activated by verbal stimuli, feeding the central processor with a schematic logical form which then has to be enriched inferentially.

Over the last few years, this view of the mind has changed within RT (and also within evolutionary psychology), especially concerning the structure of the central processor, which is also regarded to be modular (Carston, 1997; Sperber and Wilson, 2002; Wilson, 2003). The most important module, specifically a submodule of the general 'theory of mind' ability, is **the pragmatic module**, which also exhibits qualities typically associated with modules. For example, this pragmatic module is biologically endowed, only activated by a specific type of information (ostensively communicated information), and constrained by its own principle: the Communicative Principle of Relevance.

Relevance Theory as Asocial

RT has been criticized for being hyperindividualistic and for avoiding the social aspects of communication (Mey and Talbot, 1988). Sperber and Wilson (1997: 147) acknowledge that they have concentrated on the inferential activity of the individual, but inferential communication is **also** essentially social: "Inferential communication is intrinsically social, not just because it is a form of interaction, but also, less trivially, because it exploits and enlarges the scope of basic forms of social cognition. Right or wrong, this is a strong sociological claim." Although Sperber and Wilson have not studied uses of communication to

convey information about the social relationship between the interlocutors, they do not mean to deny its importance, or to express a lack of interest in the issues or the work done; they merely feel that, at this stage, they can best contribute to the study of human communication by taking it at its most elementary level, and abstracting away from these more complex (socially connoted) aspects (Sperber and Wilson, 1997). Hence, for them, although "so far, the contribution of relevance theory to the study of human communication has been at a fairly abstract level . . . it seems to us to have potential implications at a more concrete sociolinguistic level" (Sperber and Wilson, 1997: 148).

A proposal by Escandell-Vidal (2004) aims at integrating inferential and social issues in terms of principles and norms, respectively, and as part of a domain-specific picture of mental activity. The mind operates according to principles that are in charge of obtaining fully propositional interpretations from coded stimuli. When dealing with norms, the mind is engaged in both a long-term and a short-term task. The short-term one analyzes and categorizes incoming information, and the long-term task builds up and updates socially accepted behavior.

Empirical Evidence

A common criticism of RT is that it is highly speculative, predicting without empirical evidence the mental procedures and interpretive steps the human mind goes through in human communication. Obviously, we are dealing with an object of study, the human mind, which is highly complex and still largely unexplained.

Sperber and Wilson (2002: 143) acknowledge that in much pragmatic research, there is a certain reluctance to get down to experimentation. However, relevance theorists have been particularly eager to combine theoretical issues with all the possibilities of testing provided by the careful use of linguistic intuitions, observational data, and the experimental methods of cognitive psychology (see Wilson and Sperber, 2002b: 607, note 7 for references). Recent research has aimed at an empirical explanation of central claims of the theory. For instance, Van der Henst and Sperber (2004) review various experimental tests of the two Principles of Relevance. They claim that the hypothesis that hearers spontaneously rely on a relevance-guided interpretive procedure can be experimentally tested either by intentionally manipulating the effort required to process a stimulus or by changing the order of accessibility of several competing interpretations for the same stimulus. Another possible test is a manipulation of the effect factor by making a specific interpretation more or less likely to satisfy the expectations of relevance.

Other studies have focused on other possible areas of RT-based empirical research. Among them we can underline the ones on the Wason selection task. For example, Sperber *et al.* (1995) tested how participants derive implications from conditional statements in order of accessibility, stop when their search for relevance reaches an adequate balance of cognitive effects and processing effort, and select cards on the basis of this interpretation. The authors were able to manipulate the effort and effect factors by varying the content and context of the conditional statement, so as to elicit correct or incorrect selections at will (cf. Wilson and Sperber, 2002a: 279).

The plausibility of a Gricean maxim of truthfulness to explain human communication has also been tested (Van der Henst *et al.,* 2002). These authors showed that when people ask a stranger the time in the street they get, as a reply, "a time that is either accurate to the minute or rounded to the nearest multiple of five, depending on how useful in the circumstances they think a more accurate answer would be" (Wilson and Sperber, 2002b: 598), regardless of whether the people asked have (accurate) digital watches. These rounded answers are not strictly true, but they are easier for their audience to process.

Applications

RT has been applied to a number of research areas, among which we can distinguish the following.

1. **Grammar.** For RT the interest lies in how grammatical attributes constrain the choice of a candidate interpretation. In this sense, the grammatical arrangement of utterances plays an important part throughout this cognitive contextualization. From this point of view, several aspects of grammar have been addressed, including connectives (often within a conceptual/procedural account), conditionals, modals and modality, adverbs and adverbials, mood(s), tense(s), the article, etc.
2. **Humor.** Within a relevance–theoretic approach, humor is no longer a property of texts and, instead, what we need to characterize are the audience's mental processes in the interpretation of humorous texts.

   Underlying this approach to humor lies the premise that communicators can predict and manipulate the mental states of others. Knowing that the addressee is likely to pick out the most relevant interpretation of the joke (or some part of it), the humorist may be able to produce a text that is

likely to lead to the selection of an accessible interpretation, which is then invalidated at some point. In Yus (2003), for instance, it is claimed that in many jokes the initial part has multiple interpretations, which are graded according to their accessibility. The hearer is led to select an overt (i.e., relevant) interpretation of this part of the joke. Suddenly, the hearer notices that the subsequent part has a single covert interpretation which is eventually found to be the correct one (and the one providing a coherent interpretation to the whole text) and which humorously surprises the hearer (*see* **Humor in Language; Accessibility Theory**).

3. **Media discourses**. RT has also been successfully applied to the interpretation of media discourses, including films, newspaper headlines, comics, Internet discourse, and advertising. The last one is probably one of the most extensive applications of the theory. The control over the amount of information provided, the predictability of consumers' responses, and the calculation of the effort required to process information, all typical features of the strategies by the advertisement makers, can easily be analyzed using a relevance–theoretical approach (see Tanaka, 1994).
4. **Literature**. Several studies have applied RT to literary discourse (Pilkington, 2000 is an example). Within an RT approach, literariness has to be analyzed as cognitive effects triggered by textual stimuli, involving special mental processes which, through a relevance-driven cognitive exploration, result in the marginally increased salience of a wide range of assumptions (Pilkington, 2000: 189). Because in literature it is more difficult (if not impossible) to make assumptions mutually manifest, a greater load of responsibility is laid upon the reader in extracting the intended (or, alternatively, his/her own) interpretation of the text, plus whatever feelings and emotions are associated with the comprehension of the text.
5. **Politeness**. This is a typical social feature of communication that somehow appears not to suit the individual-centered approach within RT (*see* **Politeness**). However, several studies have attempted an explanation of politeness in relevance–theoretic terms. For instance, politeness has been explained within RT as a verbal strategy compatible or incompatible with the background expectations about the current relationship holding between speaker and hearer, thus leading to different relevance-oriented interpretive paths (see Jary, 1998).
6. **Translation**. In RT-bases studies such as Gutt's (2000), there is a tendency to exploit the idea of resemblance between the intended interpretations of utterances. (For an account of relevance–theoretic applications to translation, *see* **Translation: Pragmatics**.)

Concluding Remarks

In RT, Sperber and Wilson propose a coherent cognitive account of how the human mind proceeds when attempting to select a plausible interpretation of ostensively communicated stimuli. They rely on the hypothesis that a biologically rooted search for relevance aids human beings in the inferential enrichment of typically underdetermined coded texts and utterances resulting in fully propositional interpretations.

The theory has provided insights in several debates in pragmatics and cognitive science and has been applied to a good number of research areas. Undoubtedly, RT will continue to stir fruitful intellectual debates on the explanation of human communication.

Relevance Theory: Stylistic Applications

B MacMahon, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (Sperber and Wilson, 1995) is a theory of pragmatics that differs from its Gricean predecessors in proposing a cognitive account of communication. It holds that in the understanding of any spoken or written utterance, the audience must both decode linguistic material and make inferences about what the speaker or writer intended to communicate. Two principles of relevance guide us in making these inferences. The first principle of relevance leads us to focus on information that is most relevant in our environment. The second principle of relevance is a communicative principle in which every ostensive act of communication advertises itself as worth attending to. As hearers/readers, we use these principles to derive the most relevant possible interpretations of utterances. In this technical sense, an interpretation is optimally relevant when it achieves the greatest possible number of contextual effects for the least processing effort. Contextual effects, according to the theory, might involve strengthening an existing assumption, weakening or eliminating an existing assumption, or introducing a new assumption.

Poetic Effects

In relevance theory, poetic utterances such as those containing a creative metaphor are said to achieve their effects through making available to the hearer/reader a wide array of weak implicatures. In processing this kind of utterance, the hearer/reader will explore and make connections between encyclopedic entries attached to concepts, accessing just enough of the range of available weak implicatures to make the processing effort worthwhile. Relevance Theory: Stylistic Applications

B MacMahon, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (Sperber and Wilson, 1995) is a theory of pragmatics that differs from its Gricean predecessors in proposing a cognitive account of communication. It holds that in the understanding of any spoken or written utterance, the audience must both decode linguistic material and make inferences about what the speaker or writer intended to communicate. Two principles of relevance guide us in making these inferences. The first principle of relevance leads us to focus on information that is most relevant in our environment. The second principle of relevance is a communicative principle in which every ostensive act of communication advertises itself as worth attending to. As hearers/readers, we use these principles to derive the most relevant possible interpretations of utterances. In this technical sense, an interpretation is optimally relevant when it achieves the greatest possible number of contextual effects for the least processing effort. Contextual effects, according to the theory, might involve strengthening an existing assumption, weakening or eliminating an existing assumption, or introducing a new assumption.

Poetic Effects

In relevance theory, poetic utterances such as those containing a creative metaphor are said to achieve their effects through making available to the hearer/reader a wide array of weak implicatures. In processing this kind of utterance, the hearer/reader will explore and make connections between encyclopedic entries attached to concepts, accessing just enough of the range of available weak implicatures to make the processing effort worthwhile. A difference between

poetic effects and other types of effect is that the hearer/reader is largely responsible for which particular implicatures will be derived, so interpretation is both diffuse and indeterminate.

Metaphor and Metonymy

In the relevance theory account, metaphor works by making available at least two concepts that the hearer/reader will explore, to find or construct common ground between them. Metaphor is said to be a type of 'loose use' in which the relationship between what is described and the words, and therefore concepts, used to describe it is non-identical. A distinction between this and other approaches is that relevance theory does not see metaphor as a 'non-literal' trope of language. Loose use is also at work in non-literary communication (e.g., rounding up a salary in conversation, rather than giving a precise figure), and so the relevance theory account has no need to posit an awkward and uneconomical two-stage process of interpretation in which the hearer/reader is said to abandon a literal interpretation in favor of a figurative one. Pilkington (1992, 2000) gave detailed relevance theory analysis of examples of metaphor in literary texts, among them the one in the final lines of 'Digging,' by Seamus Heaney:

> Between my finger and my thumb
> The squat pen rests. I'll dig with it.

Pilkington's analysis argued that contexts activated earlier in the poem, among other things, establish digging as a family tradition, and a worthy, productive occupation requiring stamina and application, and that these contexts are available and can be used to make a rich interpretation of the 'writing is digging' metaphor. Pilkington was careful to point out that other assumptions associated with digging may be accessed; in fact, it is crucial to the relevance theory account that the available assumptions that might contribute to the interpretation of a metaphor could not be definitively listed. What is important is that in a successful interpretation, a reader has a large number of conceptual addresses to explore for encyclopedic information around 'digging' that might relate to writing in an interesting and rewarding way. Further relevance theory discussion of metaphor is given in Vicente (1996).

Papafragou (1996) took a similar view of metonymy, arguing that the relevance theory approach has advantages over the Lakoff and Johnson (1980) model in which individual metonymic expressions are said to instantiate larger, culturally determined cognitive frameworks for metonymy, such as 'place for event.' Papafragou suggested that the Lakoff and Johnson model is one of cognitive structure, whereas the relevance theory model is one of cognitive process, and claimed that particularly creative and poetic metonymic expressions are dealt with better in the relevance theory model. The metonymic expression 'the saxophone has the flu,' in which 'the saxophone' stands metonymically for the saxophone player, is said to allow for the derivation of a range of weak implicatures about the saxophone player that would be unavailable in paraphrase. Papafragou also discussed the conventionalization of metonymic expressions, arguing that full conventionalization may lead to semantic change; the metonymic expression becomes coded, so losing its poetic effects. Because semantic change occurs over time, Papafragou concluded that there are likely to be intermediate cases between creative and lexicalized metonymies.

Interpretive Use

Relevance theory distinguishes between interpretation and description (Sperber and Wilson, 1995). An utterance interpretively resembles a thought, which may be either interpretive or descriptive. Descriptive thoughts represent states of affairs in the world, whereas interpretive thoughts resemble other thoughts or utterances. The notion of interpretive use is central to the relevance theory approach to irony, in which a speaker is said to use interpretively, or echo, a thought that she/he does not necessarily hold as a true (descriptive) state of affairs in the world, but that is attributed or attributable as a descriptive thought, and possibly utterance, to another real or imaginary person. At the same time as echoing another's thought in this way, a speaker using irony communicates an attitude of dissociation toward the proposition expressed by the utterance. For example, on leaving the cinema after seeing a film that she believes was terrible, Ruth says "Great film" to her companion. If she is successful, her companion will understand that Ruth is using the utterance interpretively, echoing the view perhaps of the film company, film director, people who worked on the film, the cinema management who decided to show the film, the viewers who may have enjoyed the film, etc., and is at the same time dissociating herself from this view. The attitude communicated toward an echoic utterance can vary along a continuum from endorsement to scathing dissociation.

MacMahon (1996) has explored the notion of interpretive use in relation to literature, arguing that it is a powerful explanatory concept in the consideration of how literature communicates through the use of voice. In an analysis of Robert Browning's 'My last duchess,' MacMahon showed that the dramatic monologue allows the poet to dissociate from

the utterances of a sinister and threatening fictional speaker in a way that has much stronger effects than would an attempt to convey the same sentiments in a descriptive way. This analysis suggested that part of the strength of these effects relies on the embedded communicative situation between the imagined speaker, a 16th-century duke, and his silent hearer. The fictional duke skillfully makes available a complex set of implicatures, including the suggestion that he arranged for the death of his late wife, to intimidate his hearer, and the reader to some extent experiences the same intimidating effects. Elsewhere MacMahon (2001) explored the possibility of viewing less obvious examples of poetry as interpretive use, considering the communication of fluctuating attitudes of dissociation and endorsement toward different voices, and suggesting that the use of poetic form and the present tense might indicate dissociations from assumptions held by the self in the past or at some time, but not all of the time.

Fabb (1997) made a similar, though briefer, reference to literary free indirect discourse as interpretive use of this kind, and Wilson (2000) located interpretive use, including literary examples of free indirect discourse, within recent theories of metarepresentation as an evolved cognitive capacity.

Literary Form

Alongside his discussion of metaphor, Pilkington (2000) developed the relevance explanation of poetic effects with reference to sound patterning and epizeuxis. His claim for sound patterning such as rhyme schemes was that lexical choices become to some extent predictable within a rhyming text, and that this results in less effortful psycholinguistic processing, leaving more time, as with metaphor, for lengthy exploration of encyclopedic entries associated with the lexical concepts made more easily accessible by the rhyming words. Examples of epizeuxis such as *Oh! Absalom, my son, my son* are similarly said to redirect the hearer to lexical concepts already activated, inviting further derivation of weak implicatures.

Fabb's work on literary form (2002) made innovative use of relevance theory in suggesting that forms such as sonnethood and the line in poetry may be inferred on the basis of sometimes conflicting textual evidence. For example, while we might hold the assumptions that a sonnet has 14 lines and is in iambic pentameter, a poem of 15 lines, most but not all of which are in strict iambic pentameter, is likely to be understood as resembling a sonnet. Fabb argued that this kind of resemblance is another instance of interpretive use, since there is a loose, non-identical relationship between the text and the abstract notion of sonnethood. How strongly we infer sonnethood will depend on the degree of resemblance between the poem and our abstract notion of the form, thus sonnethood (and other verse forms) may be strongly or weakly communicated, and this again coincides with the relevance theory notion that poetic effects depend on the communication of a range of potential weak implicatures. If the poem also exhibits features of other forms, such as the quatrain, the diversity of weak implicatures is complex and causes aesthetic tension, a quality central to literary communication in Fabb's analysis. A similar argument is made for the communication of the line in poetry, wherein types of evidence include rhyme, meter, parallelism, punctuation, alliteration, syntax, and layout. These aspects of a poem may also provide conflicting implicatory evidence for lineation; aesthetic tension may, for example, be achieved through syntactic parallelisms running over layout line boundaries.

Constable's approach (1998) called into question the argument that poets carefully structure their work in order to communicate a particular range of implicatures, and, while Constable accepted the relevance theory focus on intentionality in accounting for other types of communication, he raised problems with using the same approach for dealing with metrical and rhyming poetry. His empirical work on versification suggested that meter and rhyme schemes severely restrict lexical choices available to the poet, and that this restriction results in a more random generation of implicatures than might be expected in other relevance theory accounts.

Reading Literature and Authorial Intention

Clark's work (1996) showed how relevance theory might explain possible interpretations of a short story and, like Fabb, explored the ways in which conflicting textual and contextual evidence makes literary implicatures indeterminate and inconclusive. He drew attention to the possibility that different inferences may be drawn in superficial or lengthier, deeper readings of literary texts, and made a distinction between implications and implicatures, showing that some of the complexities of reading a literary text, in this case prose fiction, involve implications within the text's fictional world being interpretable as implicatures in the communicative act between author and reader.

Intentionality in literary communication is a focus of Mackenzie's work (2002), in which it is argued that reading literature involves a suspension of the usual constraint that interpretations should derive only those implicatures that can reasonably be assumed

to have been intended by the speaker. Mackenzie argued that in the reading of literature, the search for relevance to the reader takes precedence over the assumption of communicative intentions, hence the possibility of widely divergent readings of the same text.

Religion and Literacy

J F A Sawyer, Perugia, Italy

The influence of religion on the spread of literacy has frequently been significant. It was the stated aim of many missionaries, for example, particularly Christian and Buddhist, to provide the means whereby as many people as possible could read sacred texts in their own language. In order to be able to provide people with texts in the vernacular, they were thus in many cases the first to devise scripts for languages that had previously never been written down. Among notable early Christian examples are Wulfila (Ulfilas), who designed the Gothic script (4th century C.E.); Mesrop, who invented the Armenian alphabet (5th century C.E.); and the Greek monks Cyril and Methodios, who invented what later came to be known as the Cyrillic alphabet (9th century C.E.), in which Russian and other Slavic languages are written. In Africa, the earliest extant Bantu text, a Kongo translation of a catechism, was published in 1624 by a Jesuit missionary, and in North America the Puritan John Eliot devised a writing system for the Massachuset language, in which a complete Bible was published in 1663. A Korean translation of the Bible by the Scottish missionary John Ross (1842–1915) was a major factor in the success of the indigenous Korean alphabet in use today.

The earliest Buddhist missionaries to China, Japan, and Central Asia translated their texts into the vernacular with the same zeal as the Christians. The first Chinese translations of Buddhist texts date from as early as the 2nd century B.C.E., and in the 4th century C.E., under the direction of Kumarajiva (344–413), perhaps the greatest of the Buddhist translators, a Translations Bureau was established, employing between 500 and 800 people. The entry of Buddhism into Japan led to the Chinese writing system's being adopted there by the 6th century C.E. and also to the evolution around 800 C.E. of a distinctive Japanese writing system, from which the modern kana syllabaries are derived. It was Buddhist missionaries who invented the Tibetan script in the 7th century C.E., and subsequently the Tibetan priest Phagspa, under the patronage of Kublai Khan (1214–1294), who designed the first Mongol script.

The invention of printing, crucial to the spread of literacy, was likewise in many cases closely connected with religion. In China and Japan the earliest use of

to have been intended by the speaker. Mackenzie argued that in the reading of literature, the search for relevance to the reader takes precedence over the assumption of communicative intentions, hence the possibility of widely divergent readings of the same text.

Religion and Literacy

J F A Sawyer, Perugia, Italy

© 2006 Elsevier Ltd. All rights reserved.

The influence of religion on the spread of literacy has frequently been significant. It was the stated aim of many missionaries, for example, particularly Christian and Buddhist, to provide the means whereby as many people as possible could read sacred texts in their own language. In order to be able to provide people with texts in the vernacular, they were thus in many cases the first to devise scripts for languages that had previously never been written down. Among notable early Christian examples are Wulfila (Ulfilas), who designed the Gothic script (4th century C.E.); Mesrop, who invented the Armenian alphabet (5th century C.E.); and the Greek monks Cyril and Methodios, who invented what later came to be known as the Cyrillic alphabet (9th century C.E.), in which Russian and other Slavic languages are written. In Africa, the earliest extant Bantu text, a Kongo translation of a catechism, was published in 1624 by a Jesuit missionary, and in North America the Puritan John Eliot devised a writing system for the Massachuset language, in which a complete Bible was published in 1663. A Korean translation of the Bible by the Scottish missionary John Ross (1842–1915) was a major factor in the success of the indigenous Korean alphabet in use today.

The earliest Buddhist missionaries to China, Japan, and Central Asia translated their texts into the vernacular with the same zeal as the Christians. The first Chinese translations of Buddhist texts date from as early as the 2nd century B.C.E., and in the 4th century C.E., under the direction of Kumarajiva (344–413), perhaps the greatest of the Buddhist translators, a Translations Bureau was established, employing between 500 and 800 people. The entry of Buddhism into Japan led to the Chinese writing system's being adopted there by the 6th century C.E. and also to the evolution around 800 C.E. of a distinctive Japanese writing system, from which the modern kana syllabaries are derived. It was Buddhist missionaries who invented the Tibetan script in the 7th century C.E., and subsequently the Tibetan priest Phagspa, under the patronage of Kublai Khan (1214–1294), who designed the first Mongol script.

The invention of printing, crucial to the spread of literacy, was likewise in many cases closely connected with religion. In China and Japan the earliest use of

woodblock printing was in the mass reproduction of religious texts, including one million copies of certain Buddhist prayers and charms, printed by imperial order in 770 C.E., and the Diamond Sutra, the earliest printed book to have survived (868 C.E.). The role of the Christian church in the development of printing in Europe was no less significant. The first type-printed documents in Europe were a set of Papal Indulgences (Mainz, 1454), and the first complete printed book was the celebrated Gutenberg Bible (c. 1455). From the 16th century on, the dissemination of printed vernacular versions of the Bible, together with the writings of Martin Luther and other Reformers, was undoubtedly an important factor in the spread of literacy in Europe, even to the lower orders of society. The first document to be printed in the Americas was a catechism printed in the Nahuatl language in Mexico City in 1539, and it was Jesuit missionaries who introduced printing with movable metal type into Japan in 1590.

In Jewish tradition, the written form of Hebrew scripture was always important. According to biblical legend, parts of the Hebrew Bible were originally "written on tablets of stone with the finger of God" (Exodus 31:18; cf. 1 Chronicles 28:19) or copied by ancient Israel's leaders (e.g., Deuteronomy 17:18; Joshua 8:32). The earliest Jewish term for the Jews' sacred text is *ha-katub* 'the written' (*sc.*, word, verse, passage), from which the term 'scripture' (Latin *scriptura*) is derived, and the centerpiece of synagogue architecture is the sacred ark containing scrolls of the Torah. Reading and writing – and not only Hebrew, the sacred language of Judaism – have thus from ancient times been very high on the agenda of Jewish educators. The first text on which the ancient rabbis' children practised their reading skills, we are told, was the biblical book of Leviticus, partly because it has a high proportion of familiar, everyday words like 'hoopoe' and 'griddle,' rare in other books of the Bible, and partly because the repetition characteristic of ritual codes can be pedagogically helpful.

The Reformers' emphasis on individual judgment and the ability to read for oneself contributed much to the spread of literacy. Two notable precursors of the Reformation, John Wycliffe (1330–1384) in England and Jan Hus (c. 1369–1415) in Bohemia, for example, did much to make vernacular translations available as widely as possible. The vernacular version of the Bible by William Tyndale (c. 1494–1536) was written in a language so close to common speech that even "a boy that driveth the plough" could understand it. Through King James's Authorized Version of 1611, which was heavily dependent on it, Tyndale's Bible had an inestimable influence on the English language. One might refer also to the lasting impact of Dante Alighieri (1265–1321) and Martin Luther (1483–1546) on two other European languages. It was due to Dante that Latin, hitherto the only literary language there was and one with a very restricted readership, gave way to an "illustrious vernacular" that was to become the everyday language of the Italians. Luther, more explicitly religious than Dante, also wrote in a language accessible to all, and his writings, especially his German Bible, left an indelible mark on the style and vocabulary of the German language.

In the 20th century, the Summer Institute of Linguistics, founded in 1934, together with its sister organization, the Wycliffe Bible Translators, and the United Bible Societies (an association with member societies in more than 100 countries), contributed significantly to the study and teaching of countless languages worldwide, most of them known till recently only in oral form and many of them spoken by only a relatively small number of people. It is in fact a stated goal of these missionary or quasi-missionary organizations to assist local government and private agencies in establishing literacy programs suited to local conditions and needs. In this they are following a well-established tradition going back to pioneers like the Quaker Hannah Kilham (1774–1852), who set up West Africa's first vernacular literacy program, in Sierra Leone. Under the leadership of such distinguished linguists as Kenneth Pike (1912–2000) and Eugene Nida (1914–), the Summer Institute has produced, not only translations of the Bible into hundreds of languages worldwide, but also grammars, dictionaries, and textbooks. By means of painstaking field research, the application of the most up-to-date linguistic theory, and the employment of native speakers, the Institute aims to ensure that its efforts related to literacy are of the highest quality and as effective as possible.

In some cases, religion has had the opposite effect and actually been an obstruction to ordinary people's access to the skills of reading and writing. The religious establishment in medieval Europe, for example, sought to prevent ordinary people from reading the text of the Bible in the vernacular. Jan Hus was burned at the stake in 1415, and William Tyndale was executed in 1536. The terms 'Church Latin,' 'Church Slavonic,' and the like embody an exclusivist attitude toward reading and writing skills, and before the Reformation the role of the priest in Catholic and Orthodox countries as a general rule contributed little to the spread of literacy among ordinary people. Much effort was invested instead in beautiful though expensive alternatives to literacy education, such as stained glass windows.

A similar situation existed in India, where the scripts in which Sanskrit and Hindi are written were known

as Brahmi 'divine' and subsequently Devanagari 'the script of the city of the gods,' and reading and writing were for centuries mainly the preserve of specially trained cultic personnel. Even after the invention of writing in ancient India, priority in the Hindu religion, in a situation exactly the reverse of that in Judaism, was always given to oral tradition, meticulously handed down from generation to generation by extraordinary feats of memory. The use of written texts in ritual was actually condemned. In ancient Persia the Zoroastrian priests likewise taught that their sacred text, the Avesta, believed to contain the actual words of their founder, should never be written down. According to Julius Caesar, in *Gallic war* 6.14, this was also a characteristic of the Druids, who did not want their sacred literature to be read by outsiders. A significant factor in both these examples of religious opposition to the use of writing was probably that neither the Zoroastrians nor the Druids ever had a special sacred script associated with their sacred texts, as had the Jews (Hebrew), Muslims (Arabic), Hindus (Devanagari), and Sikhs (Gurmukhi).

The spread of Islam throughout Africa and Asia is another example of the negative effect a religion can have on the spread of literacy. Since Arabic was the language in which the word of God was revealed, Muslim law forbade the translation of the Qur'an into the vernacular and vigorously promoted the teaching of Arabic in preference to any other language. There were translations such as those into medieval Persian and Ottoman Turkish, but these never acquired the same status or authority as did Luther's German Bible or the Authorized Version. Thus students at the Qur'an schools, which sprang up wherever Islam was to be found, normally learned to read and write Arabic, with varying degrees of success, before they were able to read or write in their mother tongue.

The dominance of Arabic and, in particular, the Arabic script throughout the Islamic world, not least as an exquisite form of decoration on mosques and other buildings, unique in the history of religion, undoubtedly restricted the use and development of vernacular scripts. The Arabic script was adapted, not always very successfully, for virtually every language associated with Islam. As well as the obvious examples of Persian, Urdu, and Ottoman Turkish, languages at one time written in a modified form of the Arabic script include Spanish (13th century), Malay (14th century), and Hausa (18th century). There are several interesting exceptions in which the pervasive influence of the Islamic religion on vernacular literacy was checked. The Christians of the Syriac Orthodox and Maronite churches from the 13th century wrote Arabic in a form of the Syriac script known as Garshuni. Bengali Muslims use a script similar to Sanskrit, in preference to the Perso-Arabic script employed by the vast majority of Muslims in South Asia. Under Kemal Atatürk (1881–1938), Turkey abandoned the Arabic script in favor of an adaptation of the Roman writing system that is a much simpler and more effective medium for the Turkish language.

The latest UNESCO statistics (see Table 1) show that in those areas of the developing world where the influence of Islam and in particular the Arabic language was most profound, that is to say, the Arab States, Sub-Saharan Africa, and South and West Asia, the total rates of illiteracy are consistently 10–20% higher than in East Asia or in Latin America and the Caribbean. Certainly many other factors are

Table 1 Youth literacy and illiteracy by region

Introduction

Religion is the conviction that there is more to the universe than can be immediately apprehended by human sensory means and that communication with that 'more' is feasible and desirable. One of the principal means of this communication has been human language, and this article aims to give (1) a brief account of the part that language can play in this and (2) a guide to other, more specific, articles in the encyclopedia.

Several aspects of life impel the human race toward religious approaches: desire for success in hunting animals, efforts to provide food by raising animals or growing plants, and the need to be kept from danger (predators or natural disasters). One of the strongest motivations toward religious thought and action is the desire to understand and account for phenomena that are especially frightening.

Language and the 'Numinous'

In unusual circumstances, humans have always experienced strange, particularly vivid emotions, including awe, fascination, and sometimes an awareness of forces outside their immediate observable environment. For example, in the Hebrew scriptures (Exodus 3.2–3) Moses sees a bush that is on fire but that does not get burned up: by this means, Moses' mind is focused on God, who can then speak to him.

Such circumstances are most frequently threatening, such as the danger of our own death, pain and suffering, the death of someone close to us, being alone for longer than usual, or calamitous weather conditions. Theologians have coined the term 'numinous' to refer to such experiences. The 'numinous' may sometimes also include more positive feelings: escape from the threat of death, recovery from illness, being reunited with our loved ones, and victory in battle.

One element in religion is the attempt to come to terms with the numinous, to describe the strange experiences to other human beings and to explain them. In many cases, unseen extrahuman forces (gods, spirits, angels) are assumed to be at work. We are then faced with two related tasks: (1) How can the unseen be apprehended? (2) How can the experiences be shared with others?

To assist in both these tasks, humans bring in the most highly developed human communication system, language. Animal communication appears to be limited to what can be directly observed (hunger, mating, defense of territory, perceived threats), whereas human language can cope with a far wider range of situations.

The distinctive properties of human language are generally taken to arise from the structure of the human brain and the way it functions (*see* **Cognitive Science: Overview; Anatomical Asymmetries versus Variability of Language Areas of the Brain**). These properties make it possible for human beings to speak of the unseen (even to construct systems of the unreal or the impossible).

involved, and generalizations are dangerous, but it does appear that, in those areas where Buddhist and Christian missionaries had the most impact on language, that is to say, in Europe, North and South America, and East Asia and the Pacific, their efforts to enable as many people as possible to read and write in the vernacular have left a lasting legacy.

Introduction

Religion is the conviction that there is more to the universe than can be immediately apprehended by human sensory means and that communication with that 'more' is feasible and desirable. One of the principal means of this communication has been human language, and this article aims to give (1) a brief account of the part that language can play in this and (2) a guide to other, more specific, articles in the encyclopedia.

Several aspects of life impel the human race toward religious approaches: desire for success in hunting animals, efforts to provide food by raising animals or growing plants, and the need to be kept from danger (predators or natural disasters). One of the strongest motivations toward religious thought and action is the desire to understand and account for phenomena that are especially frightening.

Language and the 'Numinous'

In unusual circumstances, humans have always experienced strange, particularly vivid emotions, including awe, fascination, and sometimes an awareness of forces outside their immediate observable environment. For example, in the Hebrew scriptures (Exodus 3.2–3) Moses sees a bush that is on fire but that does not get burned up: by this means, Moses' mind is focused on God, who can then speak to him.

Such circumstances are most frequently threatening, such as the danger of our own death, pain and suffering, the death of someone close to us, being alone for longer than usual, or calamitous weather conditions. Theologians have coined the term 'numinous' to refer to such experiences. The 'numinous' may sometimes also include more positive feelings: escape from the threat of death, recovery from illness, being reunited with our loved ones, and victory in battle.

One element in religion is the attempt to come to terms with the numinous, to describe the strange experiences to other human beings and to explain them. In many cases, unseen extrahuman forces (gods, spirits, angels) are assumed to be at work. We are then faced with two related tasks: (1) How can the unseen be apprehended? (2) How can the experiences be shared with others?

To assist in both these tasks, humans bring in the most highly developed human communication system, language. Animal communication appears to be limited to what can be directly observed (hunger, mating, defense of territory, perceived threats), whereas human language can cope with a far wider range of situations.

The distinctive properties of human language are generally taken to arise from the structure of the human brain and the way it functions (*see* **Cognitive Science: Overview**; **Anatomical Asymmetries versus Variability of Language Areas of the Brain**). These properties make it possible for human beings to speak of the unseen (even to construct systems of the unreal or the impossible).

On the other hand, it is generally agreed that unseen forces and higher beings and concepts referred to by practitioners of religions must in some sense **transcend** human language and therefore cannot be exhaustively described or apprehended with full adequacy in terms of human language.

It is interesting to ask **how far** language is adequate for this task. To what extent does language give reliable results in this task? To this question different groups of people have given different answers, even groups of people within the same religious paradigm. Extreme mystics have sometimes taken the view that God completely transcends human language, whereas fundamentalists insist on the total authority of the written words of their scriptures.

Maintaining Religious Traditions as Languages Change

The words by which people approach and address their deities soon acquire a very special status in their communities. It is often the case that in order to be effective in influencing deities or other forces, these words must be **pronounced** in an accurate fashion. As the community's language undergoes changes and the old pronunciation is left behind and forgotten, this requirement begins to give rise to problems.

Believers, and especially priests or other leaders who are charged with conducting worship and ceremonial events, need to learn the old pronunciation, and this often requires the mastery of considerable technical detail by both learners and teachers. Written accounts of such technical detail have often proved to be of great value to linguists of later ages in their study of dead languages.

For instance, one of the first known detailed descriptions of the pronunciation and grammar of a language is Pānini's 'Eight Chapters' on the Sanskrit of the Vedas (*see* **Panini**; **Phonetics: Overview**), written at approximately the middle of the first millennium B.C. This work attempted to teach accurate pronunciation of the (archaic) Sanskrit language to the priests of the religion, enabling them to discharge their liturgical functions appropriately. Pānini has been described as 'the greatest grammarian of all time' (J. F. Staal), and his work has been described as 'one of the greatest monuments of human intelligence' (L. Bloomfield).

At the same time, the **ideas** expressed by the religious words (spoken or written) used by a community become authoritative. Before writing is available, these ideas are passed on from generation to generation by word of mouth. When writing becomes available, written documents come into being. Typically, often after a considerable period of discussion, decisions are made conferring canonical authority on certain selected religious writings, and in this way sacred scriptures arise (*see* **Bible**; **Judaism**; **Qur'an**).

This authority often goes hand in hand with the claim that a superhuman agency must have been at work guiding the writer in producing the document. Accounts are sometimes given of the 'how' of such guidance: these may range from passing brief comments, as, for example, Peter's statement in the Christian scriptures (2 Peter 1:21) that prophets 'spoke from God as they were carried along by the Holy Spirit,' to whole books written on the subject (for a fuller account, *see* **Inspiration and Revelation**).

Translation and Interpretation of Religious Texts

An alternative way of ensuring that religious texts continue to be understood when their language is no longer the mother tongue of the community is to make and use translations.

The process of translation raises a number of complex issues (*see* **Translation: History**; **Translational Equivalence**). Translations of religious scriptures are not exempt from such complications (*see* **Bible, English; Bible Translation into Lesser-Known Languages; Bible Translations: Ancient Versions; Qur'an**).

In particular, translation often forces a choice between equally possible interpretations of the original text. For example, in Hebrew and Greek (as in English) no distinction is recognized between 'inclusive we' (= 'I and you (and possibly others)') and 'exclusive we' (= 'I and others but not you'). Other languages, such as Tagalog (Philippines), have an obligatory distinction between these two categories, and the Bible translator must choose one or the other. Sometimes, of course, the context makes it clear whether the Hebrew or Greek 'we' is inclusive or exclusive, but there are occasions when either is equally probable; in these cases, the translation is forced to be more specific than the original text.

Translation brings into focus the problems of how texts are to be interpreted (*see* **Sacred Texts: Hermeneutics**). Groups within a religion may espouse specific interpretations and rule out others; certain interpretations may be characterized as departures from the norm ('heresies'). Authoritative texts may be written with the specific aim of defining limits of what can legitimately be said within a religion.

Languages and Varieties of Languages That Attain Religious Importance

Some languages become of paramount importance in the practice of certain religions (*see* **Islam and**

Arabic; Sanskrit; Hebrew, Biblical and Medieval; Christianity, Catholic; South Asia: Religions). In some cases, it is claimed that the language central to the religion is 'the language that God speaks' (*see* **Islam and Arabic**); then, translation into another language may be viewed as a dilution or demeaning of the message conveyed by the document in the original language (*see* **Qur'an**).

On occasion, a particular language that is not that of the original scriptures may be accorded special status within a religion: Latin in the Catholic Church is a good example (*see* **Christianity, Catholic**). For over 300 years, the English of the King James Version of the Bible had similar status within Anglican and other English-speaking churches (*see* **Bible, English**).

Special jargon or a distinctive way of speaking often becomes associated with a particular religious group (*see* **Quakerism; Rastafari Language; New Religious Movements**).

Religious Interaction between Communities

Religious customs typically go beyond the worship and liturgical customs. Ethical dealing, both within a community and between communities, is enjoined by all the great religions. In such cases, binding principles of behavior must be set out in words. Children or converts begin to learn these principles by learning the words.

Although peaceful interaction between religious communities is often the 'official policy' of the religions concerned, in practice religious differences are only too likely to lead to conflict, sometimes war. The unrest in Northern Ireland, for example, has focused on the religious differences between Catholics and Protestants. The divide between Orthodoxy (Serbs) and Catholicism (Croats) (compounded by the presence of a Muslim community) has again recently exerted its dire influence on the former Yugoslavia. South Asia has seen a great deal of conflict between Hindus and Muslims, and some between Hindus and Sikhs. Indeed, in some cases where one religious group undergoes conquest, its religion may be obliterated altogether.

Social divisions or enmity on grounds of religion often arise within a single language community: in Northern Ireland, for example, despite wide-ranging differences in religious vocabulary, Catholics and Protestants have English as a common language. Serbo-Croatian (Serbo-Croat) is generally held to be a single language, despite religious vocabulary differences and a difference in writing system (Serbian uses the Cyrillic alphabet, Croatian the Latin one). In South Asia, Hindi (the language most typically associated with Hinduism today, and written with the Devanagari syllabary) and Urdu (the language of most Moslems, and written using the Arabic writing system) share the same syntax; some scholars would argue that in essence they still form a single language (though others would say that the extensive lexical and morphological borrowing into Urdu from Western Farsi (Persian) and Standard Arabic (Arabic) has changed the language sufficiently to make it distinct from Hindi).

Specific Religions

The main religions are sometimes treated in this encyclopedia in individual articles (*see* **Judaism**). Quite often, however, the religions of a particular region can with advantage be studied together, because of their mutual influences (e.g., *see* **China: Religions; South Asia: Religions; Melanesian Religions**). Conversely, some religions require separate articles for different forms of the religion (e.g., *see* **Christianity, Catholic; Christianity, Protestant**), or for different geographical regions (*see* **Christianity in Africa; Islam in Southeast Asia**).

Some religiously important languages are treated in separate articles (*see* **Arabic; Islam and Arabic; Aramaic and Syriac; Hebrew, Biblical and Medieval**) whereas others are discussed under the heading of the religion concerned (for Church Latin *see* **Christianity, Catholic**).

Types of Language Use in Religions

Some religions, particularly those without written records or norms, may exhibit homogeneity of linguistic style across all linguistic contexts; in such cases, it might be straightforward to speak of 'a single type of religious language' within the language concerned. But in many cases, it is not so simple: the Jewish scriptures show a vast range of (sometimes overlapping) styles: myth, narrative, law, prophecy, poetry. In many religions, written liturgical forms are normally elevated in style, often veering toward the archaic; statements of doctrine and academic theological writings share features such as consistent use of technical vocabulary with scientific writings. In contrast, private prayer is much more likely to reflect everyday usage. Particular modalities of religious activity may exhibit their own stylistic features (*see* **Prayer and Meditation; Preaching; Prophecy**).

Utterances in a religious context may on occasion fall clearly outside the range of human languages actually known by the speakers. Ecstatic utterance is not unknown as a religious practice; neither is speaking in a language not already known by the

speakers (as on the day of Pentecost; cf. Acts 2). Either of these may become in some way institutionalized in the religious practice (*see* **Glossolalia**).

Thus, the term 'religious language' is, if intended to cover the language of all religious activities, something of a misnomer. However, it is nowadays used as a technical term covering, on the one hand, discourse about religion, including theological writing and statements of doctrine, and, on the other hand, discussion of how metaphorical expressions should be interpreted in religious texts (*see* **Religious Language**).

What Is Religious Language?

The term 'religious language' is, if intended to cover the language of absolutely all religious activities, something of a misnomer.

Religions without written records or norms might conceivably exhibit homogeneity of linguistic style across all linguistic contexts; in such cases it would be straightforward to speak of 'a single type of religious language' within the languag'e concerned. But few religions are that simple: the Jewish scriptures (*see* **Bible**; **Judaism**) show a vast range of genres, including myth, narrative, law, prophecy, and poetry. In many religions, written liturgical forms are normally elevated in style, sometimes poetic, often veering towards the archaic; statements of doctrine and academic theological writings share features such as consistent use of technical vocabulary with scientific writings; while the language used in private prayer is much more likely to reflect the usages of everyday language. Particular modalities of religious activity may exhibit their own stylistic features (*see* **Hymns**; **Prayer and Meditation**; **Preaching**; **Prophecy**).

In common parlance 'religious language' is often taken to mean liturgical language. However, in scholarly contexts, the term has nowadays most often been used to cover (a) discourse about religion (including academic theological writing and statements of doctrine), and its relation to other types of discourse, and (b) discussion of how religious texts should be interpreted. This article will be mainly concerned with the former area, with principal emphasis on Christianity; the latter is the subject of another article (*see* **Sacred Texts: Hermeneutics**).

Theological Discourse, the Nature of God, and Early Christianity

As early as Plato (427–347 B.C.), thinkers began to realize that a great deal of theological discourse (spoken or written) was necessarily based on analogies and figures of speech, and hence needed to be interpreted with great caution. Discourse about unobservable entities must perforce use many of the same linguistic elements (on the levels of syntax and vocabulary) as discourse about observables. And yet on the level of meaning (semantics and pragmatics), we cannot always expect this parallel between unobservable entities and observables to carry through totally; we must face the question of how far figures of speech, and analogies between the observable and the unobservable, may be pressed.

The early Christian Fathers were well aware of the difficulties in this area: in the words of Clement of Alexandria (ca. 150–215 A.D.), "we only reach in a measure to the conception of God, knowing not what He is, but what He is not." (There is a sense in which this prefigures the teaching of Saussure (1857–1913) (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**) that linguistic elements are defined, not in terms of their positive properties, but negatively, in terms of their distinctness from other linguistic elements.)

In spite of this caution, Christian thinkers have expended a good deal of effort on the attainment of maximum accuracy and precision in discourse about God. Not surprisingly, this area has been the one of most difficulty in Christian theological discourse.

speakers (as on the day of Pentecost; cf. Acts 2). Either of these may become in some way institutionalized in the religious practice (*see* **Glossolalia**).

Thus, the term 'religious language' is, if intended to cover the language of all religious activities, something of a misnomer. However, it is nowadays used as a technical term covering, on the one hand, discourse about religion, including theological writing and statements of doctrine, and, on the other hand, discussion of how metaphorical expressions should be interpreted in religious texts (*see* **Religious Language**).

In common parlance 'religious language' is often taken to mean liturgical language. However, in scholarly contexts, the term has nowadays most often been used to cover (a) discourse about religion (including academic theological writing and statements of doctrine), and its relation to other types of discourse, and (b) discussion of how religious texts should be interpreted. This article will be mainly concerned with the former area, with principal emphasis on Christianity; the latter is the subject of another article (*see* **Sacred Texts: Hermeneutics**).

Theological Discourse, the Nature of God, and Early Christianity

As early as Plato (427–347 B.C.), thinkers began to realize that a great deal of theological discourse (spoken or written) was necessarily based on analogies and figures of speech, and hence needed to be interpreted with great caution. Discourse about unobservable entities must perforce use many of the same linguistic elements (on the levels of syntax and vocabulary) as discourse about observables. And yet on the level of meaning (semantics and pragmatics), we cannot always expect this parallel between unobservable entities and observables to carry through totally; we must face the question of how far figures of speech, and analogies between the observable and the unobservable, may be pressed.

The early Christian Fathers were well aware of the difficulties in this area: in the words of Clement of Alexandria (ca. 150–215 A.D.), "we only reach in a measure to the conception of God, knowing not what He is, but what He is not." (There is a sense in which this prefigures the teaching of Saussure (1857–1913) (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**) that linguistic elements are defined, not in terms of their positive properties, but negatively, in terms of their distinctness from other linguistic elements.)

In spite of this caution, Christian thinkers have expended a good deal of effort on the attainment of maximum accuracy and precision in discourse about God. Not surprisingly, this area has been the one of most difficulty in Christian theological discourse.

Two topics in particular occupied the attention of the early Fathers: the Trinity – 'Three persons in one God' – and the Person of Christ – 'Two natures (human and divine) in one individual.'

Also in spite of this caution, in their quest for accuracy and consistency with the sacred text of the New Testament, the Fathers were not slow to characterize certain theological discourse as being erroneous; those who held the views expressed in such discourse were excluded from the main body of the church. Christianity has perhaps gone further than any other religion in its attempts to formulate an exact understanding of God in this way.

Jewish thinkers (*see* **Hebrew, Biblical and Medieval; Judaism**) have adopted a much more pragmatic view of the nature of God than Christians and have generally been more ready to live with paradoxes, contradictions, exaggerations, and even jokes, in what is said about God. It is worth noting that Muslims have in general sought to avoid difficulties of this kind by refusing to be drawn into discussions of the nature of God (*see* **Qur'an; Islam and Arabic**).

From the 2nd to the 5th century A.D., generally accepted Christian teachings on the nature of God were codified in a number of creeds – formulae agreed on by General Councils of the bishops of the church as representing the facts of God's nature. Clearly, it is consistent with logic that **trust in** a person should be based on **facts known about** that person; the very earliest Christian creed 'Jesus is Lord' asserted the **fact** of Jesus' divinity, and **trust** in him as Master. Christian faith has always required a response on both levels, but one result of insisting on increasingly detailed creeds was that the 'personal trust in the work of Jesus' aspect of faith became less important, while the 'acceptance of creedal forms' became more important. For example, the Athanasian Creed (the last of the series of creeds) incorporates anathemas ('Without doubt he shall perish everlastingly') against the person who will not accept the technical definitions of the Trinity and the Person of Christ.

Interestingly, although the 16th-century Reformers strongly wished to reassert the importance of faith as 'personal trust in Jesus,' the mainstream movements of the Reformation, such as Lutheranism, Calvinism, and Anglicanism (*see* **Christianity, Protestant**), left these creeds entirely unchallenged. The major areas under dispute at the Reformation were: the balance between the authority of Scripture and the authority of the church traditions, the relationship between 'faith' (trust in God) and 'works' (moral living), methods of church government, and the use of vernaculars in worship and Christian discourse.

On the other hand, there were 'fringe' movements, e.g., Unitarianism, which **did** challenge the creeds on matters like the Trinity and the Person of Christ. Such movements often resurrected views of God that had originated very early in the church's history and then been rejected by the Fathers as heretical.

The Enlightenment and Theological Discourse

During the Enlightenment (18th century), Unitarian approaches were further developed, resulting in the philosophical approach known as Deism. This view accepted the idea of a universe brought into being by a Creator, but rejected all supernatural notions, including revelation and the possibility of a personal relationship between a human being and God. Creeds, based as they were on sacred texts held to have been revealed, had no authority.

This period also saw the rise of modern criticism – many teachings that in earlier ages had generally been held to be factual were subjected to much more stringent questioning, and even doubt. Questions of authorship and genuineness were raised about sacred texts. Principles that had been discovered to hold in other fields began to be applied in the religious and theological sphere. Texts that had hitherto been held to be inspired by God, and therefore unique, were shown to share linguistic and formal properties with non-inspired texts. Historical, philological and literary methods could appropriately be applied to these sacred texts just as to other texts.

Modern Philosophy and Theological Discourse

In the first half of the 19th century, Auguste Comte (1798–1857) propounded the philosophical view of Positivism. Comte saw the human race of his time as ready to progress beyond a theological and metaphysical basis for thought to an outlook in which 'positive' (i.e., observable) factors were to take priority over unobservable in providing explanations for the universe and its phenomena. He urged that only studies resting on observable facts were worthy of consideration as science. His influence was such that in the later 19th century, a serious conflict of aims and methods was perceived between religion and science.

In the 20th century, philosophy, especially in Great Britain, became particularly concerned with the contribution of language to the philosopher's enterprise. Some of the answers that had been suggested by earlier philosophers were perceived as deficient, because many of the questions that had been posed in reaching those answers had been expressed linguistically in ways that were misleading. These misapprehensions could often be corrected by a careful

examination of the language in which questions and answers were couched. This approach is often referred to as 'analytical philosophy.'

In their heyday (the 1930s), the Vienna Circle philosophers styled themselves 'Logical Positivists,' holding that all philosophical and scientific statements were to be verified with reference to observable phenomena only. All language that dealt entirely with unobservable entities was therefore, strictly speaking, meaningless. This verdict held for all metaphysical discourse including religious language and the language of ethics.

For a while, British analytical philosophers espoused this strict form of Logical Positivism. In the 1940s and 1950s, however, it became clear that being so strict was too sweeping a conclusion. It was realized that even scientific statements did not always lend themselves to conclusive verification. For any universal statement to be completely verified, every possible instance (conceivably a nonfinite number of them) would have to be investigated: "if it is recognized that such general propositions of law are designed to cover an infinite number of cases, then it must be admitted that they cannot, even in principle, be verified conclusively" (Ayer, 1946: 37).

Falsifiability, rather than verifiability, was then suggested as the *sine qua non* of meaningfulness. A hypothesis would be shown to be false if its predictions were not borne out by observable facts. If, after many comparisons of predictions with observed facts, no discrepancies between them were recorded, it could be assumed that there was a high probability of the hypothesis being true. But there would never be any possibility that the hypothesis could be conclusively proved to be true, since it might be falsified by the very next trial.

However, just as for verification, in order to falsify any universal statement, every possible instance would have to be investigated. Hence it was agreed that problems facing theologians and metaphysicians are not different in kind from those facing scholars in various other disciplines.

It was thus possible in the 20th century to build some kind of philosophical basis for religious and theological language; for an indication of how this could be done, see Ramsey (1957).

Other Problematic Areas of Theological Discourse

Problems for theological discourse that arise in speaking of the being and nature of God (see above) are not the only difficulties. Among others, probably the most complex and disturbing is how to account for the problems of suffering – how to answer questions like: "Why does God not respond to real and urgent need by doing the good things that he could do, and that would effectually meet that need?", 'How is it that there are so many exceptions to the principle that "God protects all who trust in him"?' or "If someone suffers greatly, have they sinned against God?" A further problematic field is the question of human free-will: "How far is the human will truly free?", "Does God intervene in the workings of his creation?" and "How are human beings to cooperate with God?"

Remediation of Language Disorders in Adults

L R Cherney, Northwestern University, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Since the reports of Paul Broca in 1861 and 1865 and Carl Wernicke in 1874, there has been a long-standing interest in the nature of aphasia and the relationship between language and the brain. Yet, interest in language remediation in adults grew slowly, and it was only after World War II that most treatment strategies and techniques were developed (Basso, 2003). Today, there are many approaches to language rehabilitation for adults with acquired aphasia, and it is this heterogeneity that poses a challenge for practicing clinicians who must select the appropriate treatments for their patients.

There have been several attempts to categorize the numerous approaches to language remediation in adults. Based on a literature review of articles that were published in five major journals and that spanned approximately 20 years (1971–1991), Horner and colleagues (1994) identified six models of aphasia treatment, each of which are discussed below. Similarly, Basso (2003) presented a taxonomy of approaches to aphasia rehabilitation and their theoretical underpinnings. Basso's classification, which was based on historical trends in the latter half of the 20th century, closely agrees with the categories identified by Horner *et al.* (1994). Yet any taxonomy is a simplification – it is not always clear where one approach ends and another begins, so some therapies may be consistent with more than one approach. For example, Horner and colleagues note that of the articles they reviewed, the majority (21.7%) used a hybrid approach or multitheoretic approach. Other language therapies may not fit into any of the approaches, particularly when therapies from different countries worldwide are considered (Holland and Forbes, 1993). Nevertheless, the following six categories serve as a guide to the rich and varied treatments for aphasia. Selection of treatments occurs with consideration of patient-specific factors such as type, severity, and chronicity of the aphasia, the presence of associated impairments, and the patient's communication environments.

Taxonomy of Language Remediation Approaches

1. The Stimulation-Facilitation Approach is a term that is often used synonymously with Hildred Schuell, who proposed and supported this approach (Schuell *et al.*, 1964; Duffy and Coelho, 2001). It is based on the philosophy that, in aphasia, language is not lost, but rather cannot be accessed. Aphasia is considered to be unidimensional in nature so individuals with aphasia differ only in terms of severity, not in type of aphasia. Therefore, language rehabilitation can be essentially the same for all patients. Since the auditory modality is of prime importance in language processing and is also a key area of deficit in aphasia, treatment involves repetitive, intensive auditory stimulation. The auditory stimulation, which is designed to elicit a maximum number of responses, is sometimes paired with stimulation in other modalities. Error responses are not corrected but are followed by additional stimulation, which, if adequate, is likely to elicit a correct response.

2. In contrast to the premise that aphasia is unidimensional, proponents of the Modality Model view language as modality-bound, with aphasia being characterized as a modality-specific performance deficit that may involve one or more modalities. The goal of treatment is to remediate the specific input or output modalities, singly or in combination. One way that this can be accomplished is by systematically pairing weak and strong modalities to 'deblock' impaired performance. This principle can be applied regardless of the specific modality that is being treated. For example, when confrontation naming is difficult, repetition may be used to help the patient produce the correct response; then immediately after deblocking has occurred through the use of repetition, the target response may be accessed in the previously inaccessible modality (i.e., confrontation naming) (Weigl, 1961, cited in Basso, 2003).

Luria's functional reorganization approach, which has widely influenced aphasia research and therapy, is consistent with the modality model (Horner *et al.*, 1994). According to Luria (1963, 1970), when brain tissue is destroyed, its original function cannot be restored to its previous form but can be performed by means of a partially new neural organization. Therapy is therefore directed towards reorganization and transfer of the function to other brain structures or functional systems. With intersystemic organization, new functional systems are created through the use of other undamaged links, and the impaired function is carried out at a different level of the same functional system, either at a lower and more automatic level or at a higher and more voluntary level. Precise identification of which modalities are damaged and which are preserved makes it possible to develop and implement different training procedures.

3. The Processing Approach is based on the cognitive neuropsychological models of normal language

processes that have been developed for specific language tasks such as reading, spelling, naming, or sentence production (Hillis, 2001). These information processing models assume that a complex cognitive function consists of a system of distributed and interconnected modules or mental representations that allow for processing of different types of information in cascade fashion. The representations and processes do not necessarily correspond to locations in the brain, but reflect functional components of a cognitive operation. Rehabilitation begins for each individual patient with identifying which cognitive processes and representations underlying the language task are impaired and which processes and representations are intact. For example, the task of reading words aloud involves the graphemic input lexicon, while repetition of words involves the phonological input lexicon. However, both tasks involve the semantic system and the phonological output lexicon. By comparing performance across tasks, inferences about the integrity of these cognitive processes can be made. Treatment then focuses on either the remediation of the impaired cognitive processes, compensation via the intact cognitive processes, or both. The primary contribution of the Processing Approach is that it guides the choice of interventions; however, it does not provide direct motivation for specific treatment strategies (Hillis, 2001). There are many studies, mostly single case descriptions, in which cognitive analyses have been used to focus treatment; examples can be found in Hillis (2002).

4. Several treatment approaches are based on the premise that the minor hemisphere (i.e., the hemisphere that is nondominant for language) has specific abilities, such as visual-spatial, affective-prosodic, and paralinguistic abilities, that can be used to facilitate communication. Melodic Intonation Therapy (MIT) is perhaps the best known of these treatment approaches (Sparks, 2001). It is a hierarchically structured program that uses intonation and rhythm to increase the patient's ability to independently produce high-probability phrases and sentences. The steps of MIT range from intoning a melodic line and hand tapping to answering questions using drilled phrases and sentences. Other remediation approaches that are consistent with the Minor Hemisphere Mediation Model utilize drawing as a communicative function (Lyon, 1995) and encourage humor within the therapy session (Simmons-Mackie, 2004).

5. The Linguistic (Neurolinguistic) approach is based on the principle that language has an internal organization that can be described by a specialized system of rules. In aphasia, there is disruption of lexical-semantic, syntactic, and/or phonologic performance. Treatment therefore focuses on restoring language performance, using neurolinguistic principles that are specific for each linguistic impairment. For example, the Sentence Production Program for Aphasia (Helm-Estabrooks and Nicholas, 2000) systematically trains syntax using a story completion format. Selection of syntactic structures was based on a study of agrammatism that identified a hierarchy of difficulty across 14 grammatical constructions, with imperative intransitive statements being the easiest and future tense statements the most difficult. Another sentence-production training program, Cuing Verb Treatments, is based on the notion that the verb is the central constituent in sentence structure (Loverso *et al.*, 1986, cited in Thompson, 2001). In this approach, verbs are presented as the central core of the simple active sentence; patients are trained to produce the verb and, in response to a wh-question cuing strategy, also specific sentence constituents (usually noun phrases) that are assigned to various thematic roles by the verb (e.g., agent, theme).

Based on aspects of formal linguistic theory and neurolingusitic research and consistent with Chomsky's conceptual framework, Thompson and colleagues have developed a series of treatment strategies that use the underlying canonical form of complex sentences to improve sentence production (Thompson, 2001). Procedures target the underlying linguistic representations of sentences rather than treating the surface representation that is manifested in word order. Subjects are taught to recognize the verb, its arguments, and the arguments' thematic roles in active declarative forms of noncanonical sentences. Instruction concerning the movement of various sentence constituents are provided, and subjects are taken through the proper movement to derive the surface form of target sentences such as wh-questions. Additional morphemes required in the surface form of various sentences are provided and inserted into sentence frames. Once the noncanonical form is derived, subjects are required to orally produce them.

6. In the Functional Communication or Pragmatic approach, therapists are not interested in the accuracy of the linguistic message but focus on the patient's ability to communicate the intent of the message. Communication involves more than just speaking and understanding – it reflects the application of pragmatic rules and the ability to use language in a context. Therefore, treatment includes compensatory strategies for circumventing communication breakdown as well as strategies for communication breakdown repair. One of the best-known pragmatic approaches is PACE (Promoting Aphasic's Communicative Effectiveness) (Davis and Wilcox, 1985). In the PACE technique, four major treatment principles have been delineated in an attempt to incorporate rules of

natural communication into semi-structured treatment: the clinician and patient participate equally as senders and receivers of messages; the interaction incorporates the exchange of new information between clinician and patient; patients freely choose the channels through which they will communicate, such as words, gestures, drawing, or any other communication device; and the clinician's feedback is based on the patient's success in communicating the message. Extending treatment into natural communication settings and ensuring a positive communication environment through partner training, removal of environmental barriers to participation, and conversational supports are also consistent with a functional approach (Kagan, 1998; Lubinski, 2001).

Biological Approach to Language Remediation

As we acquire new knowledge about aphasia and brain-behavior relations, additional approaches to treatment that are not easily categorized with the present taxonomy are emerging. For example, Small (2004) has advocated for a biological model of aphasia rehabilitation, in which the goal of remediation is to alter brain anatomy and physiology so that language function can be restored. In order to effect the necessary neural changes, both novel biological treatments and speech-language treatment are necessary. While the biological treatment stimulates or repairs the injured brain area, language treatments are provided to retrain the new circuitry and integrate it with the preserved, existing tissue.

Intervening in the biology of the brain will have direct effects on language recovery. Pharmacotherapy is the most frequently used biological therapy for aphasia. To date, the effects of three groups of neurotransmitters on language deficits in aphasia have been investigated: dopamine agonists such as bromocriptine (Gupta and Mlcoch, 1992; Gupta *et al.,* 1995); dextro-amphetamine and other agents that affect catecholamine systems (Walker-Batson *et al*., 2001); and the nootropic agent, piracetam (Huber *et al.,* 1997). While its mechanism is not fully understood, it has been suggested that piracetam exerts its effect by improving cognition through cholinergic and excitatory amine neurotransmission (Huber *et al.,* 1997). While pharmacotherapy is not yet proven, Small (2004) suggests that it has promise, but only when accompanied by concommitant language therapy.

Another example of a biological therapy for language remediation in adults is repetitive transcranial magnetic stimulation (rTMS) (Martin *et al.,* 2004). Based on the premise that overactivity of the right hemisphere language homologues may be maladaptive and interfere with, rather than promote, aphasia recovery, rTMS was applied to the right hemisphere to reduce its cortical excitability. Preliminary results obtained in four individuals with chronic nonfluent aphasia indicated improved picture naming following 10 sessions of rTMS. Other types of cortical stimulation techniques and even neural transplantation may, in the future, provide promise – especially when linked with intensive language treatment (Small, 2004).

Treatment Efficacy and Effectiveness

Any discussion about language remediation in adults must also address the basic question of whether aphasia treatment works. To date, the historical record of clinical outcomes for treatments of aphasia is extensive (Cherney and Robey, 2001). Over time, experimental methodologies in the field of aphasia have improved (e.g., measuring the change in communication behavior from pre-test to post-test; controlling for time post onset; setting clear exclusion and inclusion criteria to establish homogeneous groups; introducing no-treatment control groups using deferred treatment groups; random assignment; and controls on the type(s), amount, and duration of treatment), so that findings have become less ambiguous and support the conclusion that treatment for aphasia is both efficacious and effective. While there are relatively few randomized clinical trials of aphasia treatment (Greener *et al.*, 2000), over 100 single-subject aphasia treatment studies have appeared in the literature. In addition, meta-analyses applied to the aphasia treatment literature have concluded that aphasia treatment is effective (Greenhouse *et al.*, 1990; Whurr *et al.*, 1992; Robey, 1994, 1998). The latter meta-analyses (Robey, 1994, 1998), based on 21 studies and 55 studies respectively, have suggested several other conclusions, such as:

- recovery of treated individuals was, on average, nearly twice as extensive as the recovery of untreated individuals when treatment was begun before 3 months post onset
- treatment brought about appreciable gains, even when begun after 3 months post onset
- treatment brought about large effects even in individuals with severe aphasia
- treatment exceeding 2 hours of treatment per week brought about greater treatment effects.

Future research in the area of language remediation for adults is likely to focus on the development of new and innovative treatments that are theoretically based and demonstration of their efficacy and effectiveness, using rigorous scientific methodologies.

Remediation of Language Disorders in Children

P J Pagliano, James Cook University, Townsville, Australia

© 2006 Elsevier Ltd. All rights reserved.

Disorders of language in children involve an inability to use the rules of form (syntax, morphology, phonology), content (semantics), or pragmatics (contextual use) to understand or produce messages. Rather than solely focusing narrowly on the disorder, the educationalist's remit encompasses the whole child's complex interaction with the environment, society, and culture. Remediation as such is only a partial goal.

Language disorders become significant when they result in serious disadvantage, particularly in learning and consequently in economic, social, emotional, and/or physical well-being. They range in severity from no recognizable receptive or expressive language, qualitative disorders where language is bizarre or meaningless, through to language delay, and interrupted or partial loss. Atypical language may occur in isolation or in a constellation of other factors. The overall effect will depend on the type and degree of language disorder, the age of onset, when identified, and the quality of intervention.

Despite more than 5% of the world's child population experiencing communication impairment serious enough to require specialist assistance, many children, particularly those in developing countries, do not have access to basic medical care, such as having their hearing or vision assessed and adequate prosthetic devices prescribed. Consequently many mild communication problems that could easily be rectified in childhood are left unattended, to assume debilitating proportions in adult life. At the global level, enormous inequalities occur in the types and quality of intervention available and this inequality is evident even in the wealthiest countries, especially those with indigenous populations.

Theories to explain how a child acquires language have helped shape program design for children with language disorders (Owens, 2005). Early 20th century studies concentrating on language form and learning theory gave rise to behaviorism (Skinner, 1957), a theory based on the assumption that all behavior including language is learned. With nurture the principal driving force, children learn language through modeling, imitation, practice, and selective reinforcement. Language problems, the result of faulty reinforcement, are therefore corrected by rearranging environmental events to provide more appropriate reinforcement. Behaviorist approaches tend to be considerably successful in limited, structured clinical tasks, but are much less successful outside that narrow context in achieving communicative competence in the real world. Nevertheless, behaviorism remains an important ingredient in contemporary program design, especially in clinical settings and with children with severe to profound communication disorders, because it can be highly structured and unambiguous.

Chomsky's (1957, 1965; *see* **Chomsky, Noam (b. 1928)**) syntactic model of psycholinguistics argued that the child has an innate predisposition to use linguistic rules, particularly those of syntax. Language users generate sentences using what he referred to as a language acquisition device. In this theory, nature is paramount. Bloom (1970) narrowed the nurture–nature gap by contending that language development is predicated upon cognitive development and therefore semantics, not syntax, is regarded as being more important. Her semantic-cognitive model of psycholinguistics concluded that the child requires an active, sensorimotor involvement with the environment in order to employ language to encode existing knowledge. Dore (1974), Bruner (1975; *see* **Bruner, Jerome (b. 1916)**) and Halliday (1975; *see* **Halliday, Michael A. K. (b. 1925)**) all stressed the importance of social exchange as the motivation behind language acquisition. They argued that language is both acquired and learned through the facilitative social interactions between caregiver and child. This emphasis on pragmatics and communicative purpose enabled interventionists to widen their approach by simultaneously considering both language training and learning context.

Sociolinguistic theorists consider a potentially larger communication unit, the discourse. Many differences observed among children's communication, previously thought to be disorders or incorrect language use, are merely differences that relate to the child's social and cultural background (Heath, 1986). Discourse analysis provides another level of insight into how language and context are intertwined.

The most far-reaching international change in the treatment of language disorders in children has been educational inclusion (McCormick *et al.*, 2003). At a micro-level, inclusion is about the inalienable human right of a child to attend their local school with same aged peers and to be catered for there in ways that match identified needs. Many countries have enacted this right into legislation, thereby providing hope to those who have been excluded from mainstream society because of their inability to communicate.

(This has been all too common in the developing world.) At the macro-level, inclusion has transformed service provision by shifting the locus of control out of individual disciplines, such as speech language pathology and special education, into the mainstream arena.

The resultant, eclectic, broad-focus, inclusive approach has the potential (if properly resourced) to cater much more effectively for the diverse needs of individual children with language disorders, in the most culturally responsive ways possible. Transdisciplinary collaboration, where team members work together without traditional rigid specialization boundaries to assume roles that are determined by the prioritized communication needs of the child, has emerged as the preferred style of interaction. Team composition may change as the child grows but most often comprises the child (whenever possible), the parents or guardians, the speech language pathologist, educators (both regular and special), and other providers according to the particular needs and age of the child. Transdisciplinary teams use a written program planning document to collaborate in assessment, planning, and implementation. In the United States, for children aged from birth to 3 years, it is the Individualized Family Service Plan (IFSP), for school-aged children the Individualized Education Program (IEP), and for those 14 years or over, the Individualized Transition Plan (ITP), which prepares the student for independent, yet well integrated, adult community living. At an international level, documents such as the IFSP, IEP, or ITP facilitate ongoing collaboration. Desired learning outcomes are chosen by the child whenever possible.

For the speech language pathologist, inclusion has meant a move from clinic based one-on-one-therapy to also working in the child's day-to-day environment, such as in the child's home, out in the community, and in the classroom. It has similarly meant a move from solely relying on standardized psychometric assessment to inform the instruction/intervention process, to employing more naturalistic assessment measures (*see* **Classical Tests for Speech and Language Disorders**). The focus away from objectivity alone to encompassing more holistic approaches has brought considerable benefits, but also considerable challenges, as it is dependent upon the adequate provision of resources (human, material, and temporal).

Together with inclusion, another equally important international development has been the emergence of early intervention. Early intervention involves the provision of specialist services to very young children deemed to have environmental, biological, and/or established risks of developing communication disorders, with the goal of minimizing risks and maximizing future potential. An example of this is early cleft palate surgery accompanied by speech therapy and family support. Researchers have identified key factors that may hinder children's language development or predispose them to developing language disorders. By identifying and treating these critical factors as early as possible, reductions occur in both the number of children displaying long-term difficulties and the severity of these difficulties (Bailey *et al.*, 2001). Much early intervention focuses on promoting facilitative parent–child interactions. Through the IFSP, team members ensure the provision of ongoing high-quality programs. Instead of being marginalized, involving family members in the decision making frames them as part of the solution, not part of the problem, as in the past. Involving families in language intervention whenever possible is a highly effective strategy, which is supported by research and legislation.

Mostly intervention approaches involve a strong emphasis on early intervention, inclusion, and collaboration. They are then further tailored to fit the particular needs of individual students as elucidated above. The following section specifically considers children with hearing impairment, intellectual disability, profound multiple disabilities, impairments in communication and social reciprocity, and specific language impairment.

For children with hearing impairment, the screening of newborns ensures early identification and allows for the immediate provision of state-of-the-art technology, such as hearing aids, cochlear implants, and extensive speech language therapy. The earlier the provision, the better the outcome with spoken language and overall education (Tobey *et al.*, 2003). The three major approaches to teaching communication are oral communication, total communication (a simultaneous combination of both spoken and signed-first language), and the bilingual-bicultural approach (where the child learns the sign language of the local deaf community and its culture). This approach particularly suits deaf children of deaf parents. As no sign language has a written form, deaf children must learn a sound based language to become literate and to promote community inclusion.

Children with intellectual disability experience delays in language development with the delay roughly matching the severity of their impairment. Once again, intervention is best when it begins early, is a natural part of the child's world, involves learning by doing, and is concrete rather than abstract. Intervention follows normal developmental guidelines, involves lots of repetition and overlearning, with new information regularly highlighted and explicitly taught (Owens *et al.*, 2002). Particular attention must be given to help the child generalize language

skills. For children with profound multiple disabilities, augmentative or alternative communication (AAC) systems may be required (Mirenda, 2003). Augmentative systems support speech and language, whereas alternative systems provide substitutes. These can be either unaided such as speech reading and gesture, which require expert knowledge; or aided such as communication displays that consist of objects, photographs, words, numbers, or symbols; or electronic devices such as teletext captioning, voice recognition, and output communication aids; or amplification systems such as FM hearing aids. Although there are a number of different programs available, one that can be used by families and educators alike is a hybrid approach that combines aided-language stimulation with naturalistic language strategies and incidental teaching (Cafiero, 2001).

Impairments in communication and social reciprocity such as Autism Spectrum Disorders or Pervasive Developmental Disorders require ongoing intense early intervention that involves family members. Systematic intervention that builds on the child's strengths, focuses on pragmatic aspects of communication, and teaches for generalization is also recommended. A popular but demanding program, Applied Behavior Analysis, uses the child's interests to guide target selection and activities, thereby increasing the likelihood for skill generalization (Campbell, 2003). Grandin (2004) claims she employs a fivefold synergistic approach to manage her own autism consisting of learning social skills, micro-doses of medication, daily intense physical aerobic exercise, a gluten-free diet, and psychoeducation involving mentors to help her gain increased understanding and control of her own abilities.

Children with specific language impairment form a heterogeneous group who experience problems associated with phonology, morphology, syntax, semantics, and pragmatics. They do not have any identifiable disabilities, making it a diagnosis of exclusion. These children are usually late talkers, have delayed language development, and often experience literacy problems once they start school, hence the connection with learning difficulties. Often they miss out on early intervention because they have not been identified early enough and similarly miss out on early support in school for the same reason. Six popular clinical language intervention approaches are: imitation, modeling, focused stimulation, conventional recasting, expansion, and scaffolding (Leonard, 1988; Bernstein and Tiegerman-Faber, 2002). In the classroom, strategies employed include behavioral approaches, metacognition, reciprocal teaching, self-instructional training, focused instruction in reading and written expression, co-operative learning, peer tutoring, parents as teachers, microcomputers, and training in social skills.

In conclusion, the gradual shift in emphasis historically from attending to speech disorders to attending to language disorders (including those that relate to speech) has paralleled a change in focus from oral language to literacy (Neuman and Dickinson, 2002) and from a concentration on the disorder to thinking about the whole child in complex interaction with the environment, society, and culture. Early intervention, educational inclusion, and family involvement using transdisciplinary collaboration are core strategies in the context of which therapy is provided for children with language disorders. Remediation is one arm of therapy but more important is the child's happiness and well-being. Therapy is by committed specialist teams that also include the child and the child's family. It is holistic and culturally sensitive. Technology is an important and developing adjunct. Communication support is a human right.

Renaissance Linguistics: French Tradition

D A Kibbee, University of Illinois, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Linguistic description of French was unknown in France before the 16th century. The first works relating to the grammar of French were written in England, starting from the mid- to late-13th century and settling into a set group of texts (dialogues, orthography, morphology, lexicon) by the end of the 14th century. The most complete grammar of French and one of the best dictionaries of French available before 1600 was John Palsgrave's *Lesclarcissement de la langue françoyse* (1530; see Kibbee, 1991).

In France, the study of French got a later start, beginning only in the 1530s after Geoffroy Tory's appeal to bring French under the control of rules (in the *Champ fleury*, 1529). This motivation emphasized morphology more than syntax, and evolved into a tradition of grammatical description continued by Louis Meigret (1550), Robert Estienne (1557), and Ramus (Pierre de la Ramée; 1562 and 1572). A parallel tradition of grammars for the learning of French as a second language developed in France and the Low Countries, with Jean Pillot (1550),

quantitative synthesis of single-subject research.' *Research in Developmental Disabilities 24,* 120–138.

Linguistic description of French was unknown in France before the 16th century. The first works relating to the grammar of French were written in England, starting from the mid- to late-13th century and settling into a set group of texts (dialogues, orthography, morphology, lexicon) by the end of the 14th century. The most complete grammar of French and one of the best dictionaries of French available before 1600 was John Palsgrave's *Lesclarcissement de la langue françoyse* (1530; see Kibbee, 1991).

In France, the study of French got a later start, beginning only in the 1530s after Geoffroy Tory's appeal to bring French under the control of rules (in the *Champ fleury*, 1529). This motivation emphasized morphology more than syntax, and evolved into a tradition of grammatical description continued by Louis Meigret (1550), Robert Estienne (1557), and Ramus (Pierre de la Ramée; 1562 and 1572). A parallel tradition of grammars for the learning of French as a second language developed in France and the Low Countries, with Jean Pillot (1550),

Jean Garnier (1558), Gabriel Meurier (many works, starting from 1553), and Antoine Cauchie (1570). The study of the French lexicon developed in a flourishing dictionary tradition, although it remained during the 16th century a tradition of bilingual dictionaries, primarily French–Latin (Robert Estienne, continued and amplified by his understudies), with some French–Greek works (Budé and Henri Estienne). Collections of real and imagined etymologies (Perion 1555, Trippault 1580, H. Estienne 1565 (Book III), and Guichard 1610) added an historical component to the lexical field. These reference works provided the raw material for a lexical debate focusing on the acceptable expansion of vocabulary, primarily through introduction of dialectal and archaic words and the creation of neologisms. It involved translators, lexicographers, lawyers, and men of letters, featuring Du Bellay and Ronsard from the literary perspective, as well as Henri Estienne, Abel Mathieu, and many others from a more linguistic background.

A lively orthographic debate raged at the midpoint of the 16th century, pitting proponents of univocity (one letter should equal one sound) against conservators of etymological spelling. Meigret and Ramus led the charge of the reformers (religious as well as orthographic) and the movement largely died with them. (Meigret died ca. 1558; Ramus in the St Bartholomew's Day massacre of 1572.)

The subjective essays on French often drew on all these traditions. The evaluation of the vernacular attempted to define the 'naive puissance' of French, those features of French that distinguished it from its rivals, both ancient and modern. Henri Estienne, in his diatribes against Italian (especially 1578 and 1579), is the best-known polemicist for the French language, a tradition that continues to this day (but usually outside linguistic circles).

Morphology and Syntax

The grammarians of the 16th century started from the grammatical categories developed in the Greco–Latin tradition (especially Priscian and Donatus). This tradition is strong in the description and classification of morphology, less so in the description of syntax. Already in the 1520s, Robert Estienne published guides to the conjugation of French verbs and declension of nouns, manuals designed to help translators accurately render Latin into French. Thus, his grammar (1557) lists three different ways of forming the pluperfect 'conjunctive,' using the forms that, in the 21st century, would be called the past conditional, the pluperfect subjunctive, and the pluperfect indicative. The three are distinguished only by the conjunction used at the beginning of the clause, but because each can be used to translate the Latin pluperfect subjunctive, they are grouped in one category. Because these efforts did not describe French on its own terms, the first descriptions of French frequently included such categories as 'optative' mood in the verb conjugations and full six-case nominal and pronominal declensions. Applying such categories to French required grammarians to turn to semantic rather than morphological definitions of grammatical features, a move that paved the way for more abstract mentalist grammars in the 17th century.

Syntax in these grammars was generally limited to questions of agreement. Peculiarities in popular usage (e.g., *j'aimons*) were universally condemned, whereas the agreement of the past participle was a point of contention between the latinizing grammarians (Dubois) and those who felt more constrained by usage. Syntactic arguments were often invoked to resolve problems of morphological classification, particularly by Meigret and Ramus, but syntax in its own right held less interest for the grammarians of the 16th century than did morphology.

Jacques Dubois (Sylvius; 1489–1555)

The first grammar of French published in France was the *Isagoge in linguam gallicam* (1531), written by Jacques Dubois, a Picard physician whose medical writings were far more successful. It is divided into two parts, the *Etymologica* and the *Grammatica Latino–gallica*. The first part is an inventory of Latin–French letter correspondences, in which Dubois took no notice of the effect of context. Thus, he noted that Latin ⟨a⟩ can end up in French as ⟨a⟩, ⟨e⟩, ⟨i⟩, ⟨o⟩, ⟨ou⟩, ⟨ea⟩, ⟨ai⟩, or ⟨au⟩ without specifying in which contexts each of these changes took place.

In the grammar, Dubois sought to put French under the control of rules by reestablishing some parts of Latin usage that French had abandoned. His grammar followed the linguistic categories of Donatus and explained how Latin forms are rendered in French. As he considered the differences between French and Latin 'corruptions,' he sometimes recommended the substitution of Picard forms and practices for those of Paris, finding that his native dialect was closer to Latin. Meigret attacked the *Isagoge* for its failure to observe and follow usage, whereas Robert Estienne condemned its dialectal features. It was never reprinted.

Louis Meigret (?1500–?1558)

Louis Meigret, born into a well-known Lyons family, was an active translator, proponent of orthographic reform, and the author of the *Tretté de la grammere*

françoeze (1550), a much stronger effort in the description of French than the work of Dubois. It opened with a description of the sounds of French, a study at profited from his attempts at orthographic reform. Because of the radical reforms he proposed, he was forced to consider sounds rather than letters, a major advance that was largely ignored once the orthographic question was settled in favor of more traditional spelling. The rest of the grammar is devoted to the eight parts of speech, with the article (definite article only) inserted before the section on nouns. Meigret leaned toward semantic definitions of grammatical categories, but he did invoke morphology to deny the existence of neuter gender and nominal declension in French.

Robert Estienne (1503–1559) and Henri Estienne (1531–1598)

Robert Estienne's *Traicté de la grammaire françoise* (1557) is a catalogue of French morphology, derived in part from his earlier guides to conjugation and declension and in part from the works of Dubois and especially Meigret. Estienne admitted in his preface that the complaints about the orthography of Meigret's *Tretté* inspired his own efforts. Estienne's grammar is remarkable only for the clarity of its layout, testimony more to his skills as a printer than to his skills as a grammarian. Robert Estienne deserves much greater recognition for his lexicographic work (see the discussion on lexicography).

Robert's son, Henri, wrote the *Hypomneses de gallica lingua* (1582) as a supplement to his father's grammatical work, adding a long description of sounds and devoting the last 60 pages to assorted problems in syntax and semantics, including changes in meaning between preposed and postposed adjectives and various aspects of article usage. Although hardly complete, these often rich commentaries ventured into new areas in the description of French.

Ramus (Pierre de la Ramée; 1515–1572)

Ramus was an ardent opponent of scholastic philosophy, which earned him the enmity of conservative Catholic theologians at the Sorbonne. He wrote widely on philosophical, rhetorical, and grammatical questions, treating Latin and Greek grammar in the 1550s before writing the *Gramere* (1562), which he revised and transformed into traditional orthography in the *Grammaire* (1572). His basis in philosophy led Ramus to question methodological practices in grammatical description, and he made significant innovations in his insistence on using formal distinctions and complementary distribution to define grammatical categories. This organizational consistency, however, led to many grammatical inconsistencies.

The *Gramere* was divided into two parts, like Dubois's work: etymology and syntax. Etymology included the description of sounds and derivational and inflectional morphology. The strict application of his formalistic approach forced him to consider synthetic comparatives (e.g., *meilleur*) in the first part, and analytic comparative (*plus beau*) in the second. The confusion in the definition of moods led him to reject the category altogether. The basic information included in these works was taken mainly from Meigret. In the second edition, inspired by Henri Estienne's *Traicté de la conformité du langage françois avec le grec* (1565), Ramus pleaded for French grammar to be considered on its own terms, not in the light of Latin, but it was precisely his own reliance on Latin models that led him astray in many of his arguments.

Orthography and Pronunciation

Pronunciation *per se* was rarely dealt with directly in French treatises of the 16th century. Instead, grammarians concentrated on the relationship between letters and the sounds they represent. The reformers insisted on a principle of strict univocity (one letter = one sound), whereas conservatives found a variety of reasons to maintain traditional spelling. Still, in debating the merits of different spelling systems, the grammarians had to confront real issues in the description of the French sound system, such as the lack of orthographic symbols to represent the French sounds that did not exist in Latin (e.g., [ʃ], [ʒ], [z], [v], nasal vowels, schwa, etc.).

Toward the end of the century, the most significant efforts in the description of the French sound system came in works destined for foreign learners of French. Jacques Bellot (fl. 1580–1590), a native of Caen who taught French in England, developed a crude descriptive method for describing point and manner of articulation in phonetics. Claude de Sainliens (Hollyband; ?–1597), whose *French Schoolemaister* (1573) and *Frenche Littelton* (1576) remained basic texts for teaching French to English speakers well into the 17th century, offered a strong defense of traditional orthography in his *De pronuntiatione linguae gallicae* (1580), although he used diacritics to mark silent letters. Théodore de Bèze (1519–1605) wrote his excellent study *De francicae linguae recta pronuntiatione tractatus* (1584) for German-speaking students in Switzerland.

The orthographic debate was launched by Tory's *Champ fleury*, in which the printer from Bourges noted the variety of pronunciations represented by

the letters ⟨e⟩ and ⟨c⟩. Tory inspired an unknown author from Abbeville (Picardy) to compose the *Tres utile et compendieux traité de l'art et science d'orthographie gallicane* (1529), a work that proposed a more conservative (i.e., more Latinate) spelling in order to better distinguish homonyms. Dubois followed this line of reasoning when he proposed that *lisons* (from *lire*) be written *ligons* because in Latin there is a ⟨g⟩ (*legamus*). To accommodate French pronunciation and Latin etymons, Dubois experimented with some new symbols, such as ⟨ꝑ⟩ for the /s/ in *lisons*. In the same year as Dubois's treatise (1531), Tory introduced the use of the cédille. In 1533 appeared the *Briefve doctrine pour deuement escripre selon la proprieté du langaige francoys*, possibly written by Clément Marot. This work tried to regularize the use of various diacritics in French, including the apostrophe, grave and acute accents, cedilla, circumflex accent, and the diaeresis. Many of these innovations were incorporated into the last section of Etienne Dolet's *La Maniere de bien traduire d'une langue en aultre. D'advantage. De la punctuation de la langue Francoyse. Plus, Des accents d'ycelle* (1540).

Louis Meigret, Guillaume des Autels (1529–1581), and Jacques Peletier du Mans (1517–1582)

Louis Meigret also reacted quickly to Tory's appeal, composing a manifesto for orthographic reform (*Traité touchant le commun usage de l'escriture françoise auquel est debattu des faultes et abus en la vraye et ancienne puissance des letres*) and a sample text in his new orthography (his translation of Pliny the Elder). However, his reforms were considered too radical, and these works, written around 1531, were not printed until 1542 and 1543, respectively, and then only after they had been put into more standard orthography. A second edition of the treatise appeared in 1545. After some minor reforms were incorporated into Meigret's translation of Cicero (1547), the real breakthrough occurred in 1548, with the publication of Meigret's translation of Lucian's *Philopseudes*, printed entirely in Meigret's reformed orthography by Christian Wechel. This translation inspired responses from Jacques Peletier du Mans (*Dialogue de l'orthografe e prononciacion françoeze* and *Apolojie à Louis Meigret Lyonnais*, 1550) and Guillaume des Autels (*De l'antique escriture de la langue française et de sa poesie, contre l'orthographe des Maigretistes* (1548; published at the behest of Philippe Le Brun under the pseudonym Glaumalis de Vezelet). Peletier du Mans had already published (1545) in the introduction to his translation of Horace a letter outlining his sympathetic but cautious views on orthographic reform. To these critics, Meigret responded with his usual venom, in the *Défenses de Louis Meigret touchant son orthographie française contre les censures et calomnies de Glaumalis de Vezelet et de ses adhérents* and *La response de Louis Meigret à l'Apolojie de Jacques Peletier* (both 1550). Des Autels fought back with his *Replique de Guillaume des Autels aux furieuses defenses de Louis Meigret* (1551), which Meigret parried with the *Reponse de Louis Meigret à la dezesperée repliqe de Glaomalis de Vezelet, transformé en Gyllaome des Aotels* (1551).

Meigret identified three problems with French spelling: *superfluité* (letters that are not pronounced), *diminution* (sounds pronounced that are not reflected by letters), and *usurpation* (one letter is pronounced like another). By far the most common offense against reason in French orthography is the first, a weakness Peletier du Mans was willing to attack. However, he opposed most changes designed to remedy the second and third types of orthographic heresy (according to Meigret), which required more radical changes of habit.

The conservatives, represented by des Autels, argued that traditional spelling clarified the diachronic relationships between etymons and contemporary words, as well as the synchronic relationships between words of the same family. The maintenance of these etymological letters also helped foreigners learning French, presumably because they would already be conversant with Latin. Second, no spelling system could represent all the varieties of pronunciation: Each person would spell differently. Third, as pronunciation changed from period to period, spelling would be in a constant state of flux. These arguments, aided by the inertia of a literate public unwilling to master a new system, won the day, and spelling reform ever since has limited itself to minor points (e.g., the acceptance in 1835 of the spelling *-ais* for the imperfect endings). Meigret himself was forced to abandon his reformed orthography by printers who preferred profit to reason; the last translations he composed were printed in traditional orthography.

Ramus, Honorat Rambaud (fl. 1580), and Laurent Joubert (1529–1583)

In the last part of the 16th century, some appeals for reformed orthography continued to be heard – Ramus in the first edition of his *Gramere*, Rambaud in the *Declaration des abus que l'on commet en écrivant, et le moyen de les éviter et représenter naïvement les paroles* (1578), and Joubert in the *Dialogue sur la Cacographie fransaise* (a supplement to his *Traité du ris*, 1579). Rambaud went so far as to create a whole new alphabet of 52 characters that,

although simplifying sound–letter correspondences, complicated all other aspects of reading. Joubert's dialogue blamed the confusion in French spelling on Germanic influence, which, according to him, encouraged clusters of consonants (e.g., *prebstre*) lacking in the other Romance languages. By the end of the century, orthographic theory and practice had settled down into a somewhat reformed position: The exaggerated etymological letters had been dropped, but many unpronounced letters, in particular ⟨s⟩ in word-final and preconsonantal position, remained.

Lexicography

All the dictionaries relating to French in the 16th century were bilingual dictionaries, but the amount of information about the French words increased steadily, approaching French definitions of French words. That stage was finally reached with Nicot's dictionary (1606). As Latin word-lists, such as Alexander Neckham's *De ustensilibus* and John of Garland's *Synonyma* (12th century), grew into large manuscript dictionaries, such as Giovanni Balbi's *Catholicon* (14th century), the French glosses to these works became more and more informative about the vulgar language. The humanists, however, were repulsed by the medieval Latin additions to these dictionaries. Robert Estienne's work as a lexicographer grew out of his printing business, where he produced scholarly editions of newly discovered or newly collated Latin manuscripts. As the number of such editions grew, and as the translation of those editions into French became a more popular and more profitable enterprise for the printing world, the quantity and quality of French lexicography improved.

Robert Estienne's Latin and Latin–French dictionaries served as the lexicographic model for dictionaries produced all over Europe, establishing the selection of words included, the examples provided, and the order followed. The words had to be found in classical authors, the examples, where possible, in editions Estienne himself produced. Estienne replaced the topical organization preferred in most earlier dictionaries with an alphabetic organization that simplified the use of dictionaries as a reference tool.

The first Estienne-produced dictionary, the *Thesaurus linguae latinae* (1531), already included French equivalents, which were expanded in the 1536 edition. In 1538, he published his first fully bilingual dictionary, the *Dictionarium latino–gallicum* (Latin–French), which he reversed in 1539 to produce the *Dictionnaire françois–latin*. Estienne expanded this work, numbering about 9000 entries to 13 000 entries in the 1549 edition. A major step toward the creation of a French–French dictionary was the inclusion of French words drawn from 16th-century French authors in the 1549 edition. The work was reissued in 1564 by Thierry and in 1573 by Jean Nicot (1530?–1600), and the French was added to or replaced by German, Dutch, and English in a number of lexicographic works published abroad. Thus, Estienne's dictionaries had a great influence on lexicography and on the teaching of the French language across Europe. Furthermore, within France, they served to stabilize French vocabulary and standardize forms as they remained the principal lexical reference works until the dictionary of the *Académie française* (1694).

History of the French Language in the 16th Century

In the 16th century, the history of the French language served as primary evidence in the history of French institutions. The history of those institutions was itself crucial to the debate on the role of the monarchy, which in turn related to the Wars of Religion. French clearly had close affinity to Latin, and thus to Italian and Spanish. However, humanist admiration for Greek, Reform interest in Hebrew, and concurrent bursts of celtomania and xenophobia led to theories about the origin of the French language that resolutely pursued the implausible.

The thesis that French had Greek origins was supported by a number of Classical and biblical sources (Léon Trippault provided a summary in an appendix to his *Celt hellenisme, ou etymologic des mots francois tirez du graec. Plus. Preuves en general de la descente de nostre langue*, 1580). Many historians of French claimed that the Gauls spoke Greek or some closely related language. In this way, native gallican interests could be allied with the most prestigious of the ancient languages (and opposed to Italian/Latin). This linkage took on political significance in works, such as François Hotman's *Franco–gallia* (1573), in which evidence from diachronic linguistics was adduced to provide an historical basis for elected, constitutional monarchy and customary law, as opposed to divine-right absolute monarchy and Roman law.

At the same time, other scholars sought to establish links between Hebrew and French. Guillaume Postel (*Linguarum duodecim characteribus differentium alphabetum, introductio, ac legendi modus longè facilimus*, 1538) provided a basis for this work, which received occasional mention in the works of Joachim Perion (*Dialogorum de linguae Gallicœ origine, eiusque cum Grœca cognatione, libri quatuor*,

1555) and Trippault, and culminated in Estienne Guichard's *L'harmonie étymologique des langues hébraïque, chaldaïque, syriaque, en laquelle par plusieurs Antiquitez et Etymologies de toute sorte se demonstre evidemment que toutes les langues sont descendues de l'Hébraïque* (1610).

Such historical evidence was necessarily impressionistic, generally based on word-lists of fewer than 500 entries (Joachim Perion, Léon Trippault). The dangers of basing such conclusions on small lists of words led the more linguistically sophisticated Henri Estienne to argue not for a Greek origin of French, but rather closer affinity between constructions of modern French with ancient Greek (*Traicté de la conformité du langage françois avec le grec*, 1565). Even in these small word-lists, many of the etymologies were erroneous, for greater emphasis was placed on semantic similarity than on regular sound (letter) changes. One or two similar letters and a plausible story relating the meaning of French and Greek words were enough to establish the etymological link.

As the 16th century wore on, the flaws in this method became apparent. Abel Mathieu (*Devis de la langue françoyse*, 1559; *Second devis et principal propos de la langue françoyse*, 1560) established that many of the legitimate etymologies relating French to Greek words were words only recently introduced into French, in the wave of neologisms that accompanied the translation of Classical works into French. This theme was picked up by Etienne Pasquier (*Recherches sur la France*, 1560) and Claude Fauchet (*Recueil de l'origine de la langue et poesie françoise*, 1581), who first traced the history of medieval French literature. The absence of the supposedly Greek words in those texts helped destroy the myth of the Greek origins of the French language. Equally important, a new attitude toward etymology, insisting on methodical links between letters rather than on subjective impressions based on a limited portion of the complete lexical corpus, and a recognition of the difference between Vulgar Latin and Classical Latin, improved the accuracy of historical speculation. Jacques Bourgoing, counselor to the king, demonstrated the usefulness of the comparative method to correct the errors of the grecophile etymologists in his *De origine usu et ratione vulgarium vocum linguœ Gallicœ, Italicœ, & Hispanicœ, libri primi sive A, centuria una* (1583), thus setting the foundation for 17th-century historical work, such as Ménage's *Les origines de la langue française* (1650).

Subjective Appreciation of Language

The establishment of standard languages and the competition for preferred status among the modern languages in the 16th century inspired a number of observations, both within grammatical works and in special volumes dedicated to the subject, concerning the relative merits of European languages. Works, such as Du Bellay's *Deffence et illustration de la langue françoyse* (1549) and Ronsard's *Abrégé de l'art poétique* (1565), served this purpose on the literary side, whereas Henri Estienne provided the most pointed remarks from a more linguistic frame of mind (*Deux dialogues du nouveau langage françois italianizé*, 1578; *Project du livre intitulé de la precellence du langage françois*, 1579). The authors of such comments directed their attacks not only at competing vernaculars (especially Italian), but also at 'nonstandard' forms of their own language. Early in the century, dialectal forms were viewed approvingly as enriching the word stock of French, but as religious intolerance grew in the period of the Wars of Religion so too did linguistic intolerance. Meigret attacked what he labeled the 'effeminate' usage of the court, as well as the Picardisms of Dubois, only to be attacked himself for dialectal features of his native Lyonnais. Picard, Gascon, and Norman pronunciation were noted and rejected in orthographic and pronunciation texts, and a number of other dialects were noted (disapprovingly) in dictionaries. Thus, the stage was set for the linguistic absolutism of Malherbe, Vaugelas, and Bouhours in the 17th century.

Renaissance Linguistics: Spanish Tradition

J C Zamora, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

The origin of Spanish Renaissance linguistics can be traced to Italy in the 1440s to the work of Lorenzo Valla (1407–1457). His ideas, goals, and methods decisively influenced early Spanish humanism. One of Valla's goals was the recovery of Classical Latin, rescuing it from what he perceived as the clumsiness and corruption of Medieval and Church Latin. Recovery of the language of Cicero and Virgil would make possible the rediscovery of Classical learning. Valla also wanted to discredit the canon of medieval grammarians and the scholastic philosophers who had provided the intellectual basis for medieval thought. Valla's tool to achieve both goals was philological exegesis (the use of grammar, rhetoric, and history to establish the validity of part or all of a text), which was not of his invention but which he developed and perfected (*see* **Philology and historical Linguistics**).

Humanist questioning of Medieval Latin texts presented a problem for the Church, since much of Church doctrine had resulted from readings of those texts. The Church was also troubled by humanism's rejection of scholastic philosophy because it served as the base for medieval theology. The resulting conflict between the Church and humanism greatly affected grammatical studies during the Renaissance, to some degree everywhere in Europe but particularly in Spain.

During the early Renaissance an interest in 'vernacular humanism' paralleled the interest in 'Classical humanism.' The concern with correct usage of Latin was transferred to the vernacular languages, and it led to the writing of both grammars and treatises on the merits and values of these languages. For Spanish, one of these treatises deserves special consideration, the *Dialogo de la Lengua* (1535; written in Naples, first published in Madrid in 1737) by Juan de Valdés (ca. 1495–1541). It is an attempt to do for the Spanish language what Pietro Bembo (1470–1547) had done for Tuscan (Italian) in his *Prose della Volgar Lingua* (1525). The development of national states and the need for a unifying official language added to interest in the study of the vernaculars.

Early humanists were not interested in explanatory theories of grammar; their objective was to describe the language of the great figures of Classical antiquity, not to explain the nature of language and how it worked. Moreover, the theoretical approach to language with which they were familiar, speculative grammar, had been developed within Aristotelian scholasticism, which they rejected. However, toward the end of the first half of the 16th century, when the goals of the humanist movement had been achieved, interest in theory again developed. With regard to linguistics, the Renaissance can be divided into two major periods. The first one is dominated by descriptivism and the second one by an interest in explanatory theories of language and grammar. In Spanish Renaissance linguistics one finds the same two periods, the second one beginning toward the 1580s. Each period in Spain was dominated by one major figure, Nebrija and Sanctius, respectively. Those

Renaissance Linguistics: Spanish Tradition

J C Zamora, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

The origin of Spanish Renaissance linguistics can be traced to Italy in the 1440s to the work of Lorenzo Valla (1407–1457). His ideas, goals, and methods decisively influenced early Spanish humanism. One of Valla's goals was the recovery of Classical Latin, rescuing it from what he perceived as the clumsiness and corruption of Medieval and Church Latin. Recovery of the language of Cicero and Virgil would make possible the rediscovery of Classical learning. Valla also wanted to discredit the canon of medieval grammarians and the scholastic philosophers who had provided the intellectual basis for medieval thought. Valla's tool to achieve both goals was philological exegesis (the use of grammar, rhetoric, and history to establish the validity of part or all of a text), which was not of his invention but which he developed and perfected (*see* **Philology and historical Linguistics**).

Humanist questioning of Medieval Latin texts presented a problem for the Church, since much of Church doctrine had resulted from readings of those texts. The Church was also troubled by humanism's rejection of scholastic philosophy because it served as the base for medieval theology. The resulting conflict between the Church and humanism greatly affected grammatical studies during the Renaissance, to some degree everywhere in Europe but particularly in Spain.

During the early Renaissance an interest in 'vernacular humanism' paralleled the interest in 'Classical humanism.' The concern with correct usage of Latin was transferred to the vernacular languages, and it led to the writing of both grammars and treatises on the merits and values of these languages. For Spanish, one of these treatises deserves special consideration, the *Dialogo de la Lengua* (1535; written in Naples, first published in Madrid in 1737) by Juan de Valdés (ca. 1495–1541). It is an attempt to do for the Spanish language what Pietro Bembo (1470–1547) had done for Tuscan (Italian) in his *Prose della Volgar Lingua* (1525). The development of national states and the need for a unifying official language added to interest in the study of the vernaculars.

Early humanists were not interested in explanatory theories of grammar; their objective was to describe the language of the great figures of Classical antiquity, not to explain the nature of language and how it worked. Moreover, the theoretical approach to language with which they were familiar, speculative grammar, had been developed within Aristotelian scholasticism, which they rejected. However, toward the end of the first half of the 16th century, when the goals of the humanist movement had been achieved, interest in theory again developed. With regard to linguistics, the Renaissance can be divided into two major periods. The first one is dominated by descriptivism and the second one by an interest in explanatory theories of language and grammar. In Spanish Renaissance linguistics one finds the same two periods, the second one beginning toward the 1580s. Each period in Spain was dominated by one major figure, Nebrija and Sanctius, respectively. Those

topics of Spanish linguistics that overlap the previous temporal division will be treated separately.

The Early Renaissance in Spain

Lorenzo Valla's ideas and methods spread to Spain quickly, earlier than to other areas of Europe. This is partially explained by the Spanish (Aragonese) presence in Italy. In 1440, Valla, while acting as secretary of Alfonso V of Aragon, wrote *Declamatio de Falso Credita et Ementita Donatione Constantini*, in which he first used the philogical method to expose as fraudulent the document used by the Church to claim the Italian territories of the former Roman Empire. Obviously, this favored Alfonso's claim to territories in Italy.

A more important factor was Antonio de Nebrija's humanistic training in Italy. In 1463, at age 19, Nebrija left the University of Salamanca to continue studying at the Spanish College in Bologna. He spent 7 years in Italy studying the ideas and methods of humanist philology. When he returned to Spain in 1470, Nebrija had become a devoted follower of Valla.

Antonio de Nebrija (1444–1522)

Antonio (also Elio Antonio) de Nebrija (or Lebrija, for his place of birth in southern Spain) dominated the early Renaissance in Spain through the volume, quality, and diversity of his work. He was the first to cover all the fields and languages of interest to early humanism. He wrote grammars of Latin (including a 1486 version in Castilian for Queen Isabella) as well as one of Castilian. He also wrote bilingual dictionaries of Latin and Castilian, and studies on the orthography and pronunciation of Classical Latin, Greek, and Hebrew. Nebrija also wrote dictionaries of Latin legal and medical terminology, a book on history and archeology of Spain, and other diverse works, including poetry composed in classical Latin.

Nebrija's first major work, *Introductions Latinae* (Salamanca, 1481) appeared while he was teaching at the University of Salamanca. It was an immediate success; by the time of its author's death the book had gone through at least 50 editions or printings in Spain and abroad. After Nebrija's death, the *Introductiones* was published several times during the 16th century in France and Italy. An English translation of the 1486 Castilian version appeared in England in 1631. In Spain, the *Introductiones* was the most popular text for teaching Latin until the 18th century. Its success was determined mostly by its didactic nature. Nebrija was an admirer of the Latin (Byzantine) grammarian Priscian, but he realized that Priscian wrote for students whose first language was Latin, whereas he wrote for students with no knowledge of Latin when they arrived in school; the book was the first one consciously written for students of Latin as a second language.

His dictionaries, Latin–Spanish (1492) and Spanish–Latin (ca. 1495), were models of lexicography; they represented a complete break with the medieval tradition in this kind of work. His Spanish grammar, *Gramática de la Lengua Castellana* (Salamanca, 1492), was the first complete one for a modern language. It includes books (sections) on syntax and on Spanish for foreigners, in addition to the traditional sections on orthography, pronunciation, prosody, and morphology. Rather than simply adapting and translating from Latin, Nebrija in the *Gramatica* developed a new grammatical terminology for Spanish.

In 1502, Nebrija joined the group set up in Alcalá by Cardinal Jiménez Cisneros to publish a polyglot Bible, but he abandoned Alcalá when Cisneros forbade changes in the Medieval Latin version. On returning to the University of Salamanca he tried to publish a list of biblical errors deriving from a poor knowledge of Latin, Greek, and Hebrew, but the Grand Inquisitor prohibited the publication and ordered Nebrija to surrender the list, which he did. Nebrija's problems with the Church and the Inquisition had no grave consequences, but only because of his friendship with the leaders of the Spanish Church and with the Spanish monarchs Ferdinand and Isabella. Later grammarians would not find dealing with the Inquisition as easy.

Nebrija spent his last years as a professor at the University of Alcalá, which had been founded by Cardinal Cisneros. In recognition of the importance of Nebrija's scholarship and continuing productivity, Cisneros said in the decree of appointment that the Spanish grammarian would draw a salary whether he taught or not.

Other Descriptive Grammars

Several grammars on Spanish were published before 1580, but only one in Spain proper, Baltasar Sotomayor's *Grammatica* (1565), which compares Spanish and French to facilitate the learning of the latter. Four were published in the Spanish territories of the Low Countries, in Amberes (Antwerp), or Lovaina (Louvain), all to facilitate the learning of Spanish. Two are anonymous (1555 and 1559), but the authors of the others were Gabriel Meurier and Cristobal Villalón (both 1558). Meurier's includes French as well as Spanish, whereas Villalón's is the best of this whole group. Two grammars appeared in Italy during this period, those of Giovanni Mario Alessandri

(1560) and Giovanni Miranda (1565). None is comparable in intent or content to Nebrija's.

Latin grammars were published by Bernabé de Busto (Salamanca, 1533) and Bachiller Thamara (Antwerp, 1550), both in Spanish, but only four works on the Classical languages written during this period, all by the same author, deserve consideration, and only because the author, Francisco Sánchez de las Brozas (usually referred to in Spanish as 'el Brocense' and in other languages as 'Sanctius') is the major figure of the second part of the Renaissance in Spain. Two of his introductory textbooks on Latin were published in Lyon in 1562; another one, written in Spanish, was published in Spain in 1576. Sanctius published an introductory Greek grammar in Antwerp in 1581. His major work, the *Minerva*, is discussed later.

Certainly worthy of mention is the work on Amerindian languages done by Spanish missionaries in the New World. They had composed by 1571 five grammars of Mexican languages (one of Tarasco and four of Nahua) and one of the Quechua of Peru. All had attached vocabularies in the local language and Spanish. This was achieved while there were many modern European languages, English and German among them, for which full grammars had not yet been written.

The Late Renaissance in Spain

Descriptive grammars of Spanish continued to appear during the second part of the Spanish linguistic Renaissance; many of them, by authors of other nationalities, were published abroad, in England, France, Germany, and Italy. Of those published in Spain the only one worthy of mention is Bartolomé Jiménez Patón's *Instituciones de la Gramática Española* (Baeza, 1614).

The first dictionary of Spanish, by Sebastián de Covarrubias (1539–1613), the *Tesoro de la Lengua Castellana o Española*, was first published in Madrid in 1611. Covarrubias included archaisms, neologisms, loan-words (many of Amerindian origin; e.g., *canoa* 'canoe' and *hamaca* 'hammock'), and vulgarisms, labeling them as such. Definitions are usually precise and concise but complete, except when dealing with terms related to history, geography, the arts, religion, mythology, or the exotic. The entries for the latter resemble those of the medieval encyclopedic treatises, as do many of his often incorrect etymologies. The book, however, is of great value for its documentation of the lexicon of the period and for the interpretation of the writings of Covarrubias's contemporaries.

Sanctius (1523–1600)

Francisco Sánchez de las Brozas (Sanctius or 'el Brocense') was born in western Spain but spent his early life in the service of the Portuguese court. After returning to Spain at age 20 he dedicated himself almost entirely to the academic life. He studied at the Universities of Valladolid and Salamanca, and in 1554 he became a *praeceptor* 'lecturer' at the Trilingual (Latin, Greek, and Hebrew) College of the latter university. In 1573, he obtained the Chair of Rhetoric and later those of Greek and Latin, all at Salamanca. In addition to those books mentioned previously, he wrote treatises on rhetoric, philosophy, and theology, as well as translations and editions of literary works.

In 1584, Sanctius was ordered to appear before the Inquisitorial Tribunal in Valladolid, reprimanded for his textual interpretation, and warned that future errors would be severely punished. In 1593, the year of his retirement from the university, he was again investigated by the Inquisition. Sanctius died before the end of his trial and was denied burial honors. The Inquisition's preoccupation with Renaissance philology and grammar is evident from the pejorative use of the word *gramático* 'grammarian' during the trial when addressing Sanctius. This explains why Sanctius (and later Correas) never wrote a treatise on grammatical theory, on linguistics as such. His ideas on the subject have to be culled from a book that is in appearance nothing more than a study of Latin grammar, *Minerva: seu de Causis Linguae Latinae* (Salamanca, 1587).

Sanctius's approach to grammar and language can be placed in the same mentalist, rationalist tradition of medieval speculative grammar that developed the ideas first posited in Aristotle's *Peri hermeneias*. The full title of his *Minerva* shows that he acknowledged a debt to Julius Caesar Scaliger's (1484–1558) *De Causis Linguae Latinae* (1540); his influence on the Port-Royal grammarians was expressly recognized by one of the authors (Claude Lancelot) of the *Grammaire Generale et Raisonnee* (1660).

There are, however, major differences between Sanctius and those who precede or follow him. Sanctius is the only one to postulate an underlying structure that is syntactic rather than semantic in nature, as well as the only one to postulate a grammatical or syntactic system rather than a purely logical one. He constantly justify what he says by referring to *grammaticae ratio* 'grammatical system or logic.' His underlying structure not only includes elements that must be understood as deleted from the surface but also includes grammatical forms that, as Sanctius shows, are essential at that level but cannot appear in the surface. In the *Minerva*, the perfect grammari-

an is defined as one who in Cicero's or Virgil's books will identify which words are nouns, which are verbs, as well as other matters that concern only grammar, even if he does not understand the meanings of the words. Not until much later can one find a statement that so clearly upholds the autonomy of grammar. Sanctius did not develop a system of rules to relate his two levels of syntactic structures, but the *Minerva* is closer to modern generative grammar than any other work written before the 20th century.

Other Theoretical Grammarians

Two other Spanish grammarians of the 17th century showed a major interest in grammatical theory, Correas and Caramuel. The former applied and developed the ideas of Sanctius, and the latter represented a return to late medieval grammatical thought.

Gonzalo Correas (1571?–1631) was born in the same area of western Spain as Sanctius. Correas taught Greek and Hebrew at the University of Salamanca. He published grammars of Greek, Latin, and Spanish (and a now lost one on Hebrew); edited and translated Classical works; compiled a collection of Spanish proverbs and popular sayings; and composed some minor poetry in Greek, Latin, and Spanish. In his time he was very well-known for several treatises proposing the radical reform of Spanish orthography.

Correas was the most important follower in Spain of the author of the *Minerva*. Like Sanctius, Correas never wrote a linguistic treatise as such. His ideas on grammatical theory and universal grammar appear in the *Arte Grande de la Lengua Castellana*, an excellent and lengthy grammar of Spanish finished in 1626 but not published until the 20th century, and in the *Trilingüe de Tres Lenguas* (Salamanca, 1627), which includes grammars of Spanish, Latin, and Greek – all written in Spanish. Correas held that grammar (i.e., syntax) was for the most part common to all languages, and he made use of this idea in writing the *Trilingiie*. In his treatment of syntax he closely follows Sanctius.

Juan Caramuel y Lobkowitz (1606–1682) was a bishop who subscribed to the ideas of Scholasticism. His only book on grammar, the *Grammatica Audax* (Frankfurt, 1654), dealt with Latin. He was a follower of the medieval *Modistae* and their speculative grammar, particularly of Thomas of Erfurt, whose *De Modis Significant sive Grammatica Speculativa* (ca. 1305) was at the time attributed to J. Duns Scotus (Caramuel claimed to be a follower of Duns Scotus). Caramuel's *Grammatica* anticipates the semantic and logical position of the authors of the Port-Royal grammar.

The Preoccupation with Orthography

The first treatment of the writing system of Spanish appears in Enrique de Villena's *Arte de Trovar*, completed in 1433. It is an interesting work, but it should be studied in the context of the Middle Ages rather than here. The first to treat this subject in the Renaissance was Antonio de Nebrija in his 1492 *Gramática de la Lengua Castellana* and later in his *Reglas de Orthographia en la Lengua Castellana* (Alcalá de Henares, 1517). Nebrija was perfectly aware of the difference between letter and sound of language; in the *Reglas* he very clearly stated that a letter is nothing but a mark or figure through which a sound of language is represented. In the same book, he said that humans can make an infinite number of sounds, but that each language has a limited number of specifically linguistic sounds, showing his awareness of what modern linguistics calls 'phonemes.'

Writing after the invention of printing, Nebrija shared with many of his contemporaries the preoccupation with the standardization of orthography, to the point of suggesting that the standardized form be enforced by royal decree. Spelling, Nebrija said, should show a one-to-one relationship between letters and sounds; both in the *Gramatica* and in the *Reglas* he insisted on requiring that one write as one speaks and vice versa. Nebrija proposed the reform of Spanish orthography to make it adjust to the previous ideal of biuniqueness. This concern with the correspondence between speech sounds and letters was shared up to the late 20th century by most Spanish grammarians.

The most interesting proposals for spelling reform during the later Renaissance are those of Mateo Alemán, a major literary figure whose *Ortografia Castellana* (Mexico, 1609) reflected the changes that had taken place in Spanish pronunciation since Nebrija's time, and those of Gonzalo Correas, whose *Nueva i Zierta Ortografia Kastellana* (Salamanca, 1624) and *Ortografia Kastellana Nueva i Perfeta* (Salamanca, 1630) reflect in their titles some of the changes he proposed.

Historical Linguistics

As stated previously, during the early Renaissance vernacular humanism ran parallel to Classical humanism, very often in the same author. Proponents of the merits of the vernacular languages were familiar with the mostly mythological histories of Latin and Hebrew and felt the need to give a similar historical background to their own languages. Nebrija, in the introduction to his Spanish *Gramática*, gave a nutshell history of the Spanish language; he correctly

saw Castilian as developing from the 'corruption' of Classical Latin. Since he perceived the latter as the most perfect of languages, claiming it as the ancestor could not but enhance Castilian, even if corruption was the link between the two. The idea, essentially correct, was embraced by grammarians and authors of treatises on language during most of the 16th century. However, perception of Spanish as an imperial language, spoken by the rulers of the Low Countries, most of Italy, and immense territories in the New World, Asia, and the Pacific Ocean, made scholars desire an even more illustrious beginning for the language. Spain was not in this alone; most of Europe was making fantastic claims for the particular vernacular of each country.

In this context, in 1588, 'relics' were found in Granada, among which were manuscripts supposedly dating from the first century A.D., some written in Latin and others in Castilian. Some of the documents in Castilian were attributed to St. Cecil, disciple of St. James the Apostle, patron of Spain. Until the end of the 17th century, when the Vatican declared that the relics were false, they served to validate claims that Castilian developed independently, rather than being a 'corruption' of Latin, and was at least as old as the latter. The first history of the Spanish language, Bernardo José de Aldrete's (1560–1641) *Del Origen y Principio de la Lengua Castellana O Romance que Oi se Usa en Espana*. (Rome, 1606), was written to combat this so-called 'theory of early Castilian.' José de Aldrete, although he himself was a member of the clergy, published his book in Rome to avoid conflict with the Spanish Church and Inquisition. For the same reason, rather than questioning the authenticity of the relics, he said that the documents were written in Spanish not because the language was spoken in the first century A.D. but because St. Cecil had worked the miracle of writing in a language that would not exist until 1000 years later. By giving a miracle as an alternative explanation, José de Aldrete obviously hoped to safeguard his work from attacks by the Church. José de Aldrete's book is more modern than any written on historical linguistics up to the end of the 18th century.

Dialects and Sociolects

A number of the grammarians working with the vernaculars during the Renaissance noted the geographic and social variety occurring in those languages. As early as 1535, Juan de Valdés in his *Diálogo de la Lengua* said that there were many varieties of Castilian because it was spoken in many regions, each region having vocabulary items and pronunciation that were peculiar to it. He pointed out two reasons for this variety: diversity of realms and contact with speakers from neighboring regions. In his *Del Origen y Principio*, Bernardo José de Aldrete devoted an entire chapter to dialects, calling them by that same name. José de Aldrete stated that there are as many dialects of one same language as there is geographic diversity. He pointed to differences between rural and urban speech. He stated that there is diversity even within a city, if it is large enough, as well as between speakers from lowlands and mountains in rural areas.

Sebastian de Covarrubias's *Tesoro* is the first Spanish dictionary that gives a definition of dialect. It is, Covarrubias stated, that which is peculiar to each language, through which we distinguish the speech of Old and New Castile, of Andalusia, and of other regions, where, even though the same Castilian language is spoken, there are different manners of pronunciation and of forming vocabulary; also, all other nations have these same differences that distinguish people from one province from those of another. Covarrubias often noted the regional and social usage of the words he defined.

Gonzalo Correas, in his *Arte grande*, called for a standard or norm – that of pure Castilian. This notwithstanding, he criticized some aspects of the language in Castile. Throughout the book, he discussed regional differences, those that are morphological or syntactic as well as those that occur in pronunciation and vocabulary. He even recognized social variety, indicating that this occurs because of age, social class, sex, profession or occupation, and rural or urban condition. More important, Correas stated that each social variety, each sociolect, was as valid within its context as any other, specifically indicating that the linguistic style of the court and nobility was only one part of each language, other styles being just as good and as elegant for their speakers and circumstances.

Dialectology and sociolinguistics did not come into their own until much later. However, modern linguists will not find fault in the previously discussed ideas of the Spanish Renaissance concerning geographic and social variety.

Renou, Louis (1896–1966)

K Karttunen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Louis Marie Joseph Renou, the famous French Indologist, was educated in Paris. In 1914, the war interrupted his studies, and eventually he spent 2 years as a prisoner of war. After the war, he continued Indological studies under Sylvain Lévi (also, later, Meillet, Bloch, and Foucher) and graduated in 1920. Following the example of Bergaigne, he concentrated on Vedic studies, though he originally also pursued Greek studies (P. Chantraine was his close friend). He received his Ph.D. in 1925 in Paris. In 1925 he succeeded F. Lacôte as professor of Sanskrit at Lyon but returned soon, in 1928, to Paris to succeed L. Finot at École Pratique des Hautes Études. In 1936 he succeeded A. Foucher as professor of Sanskrit at Sorbonne and, in 1946, P. Pelliot at Académie des Inscriptions et Belles-Lettres. He was visiting professor in Pune (India) in 1948–1949 and at Yale in 1953. In 1954–1956 and in 1959, he was director of Maison Franco-Japonaise in Tokyo.

Louis Renou was one of the greatest scholars of the Veda and of Indian grammatical tradition, but he was also interested in classical Sanskrit poetry. As a Vedist, he followed the example of Bergaigne, Oldenberg, and Geldner in attempting to interpret Vedic texts in their Indian context and as whole works. He was much engaged in grammatical and semantic studies. His major works include the unfinished translation and commentary of the Rigveda (*Hymnes et prières du Veda* [1938]; *Hymnes spéculatifs du Véda* [1956], and several volumes of the series *Études védiques et paninéennes*), three grammars, a manual of Sanskrit grammatical terminology, and the editions-*cum*-translations of *Pāṇini*, *La Kāśikā-vṛtti* (together with his pupil Y. Ojihara), and the *Durghatavṛtti*. Renou's *Bibliographie védique* (1931) was a basic tool of research; the work was later continued by R. N. Dandekar in Pune.

Renou was a popular teacher who even in his teaching concentrated on Sanskrit, leaving comparative linguistics to A. Minard. As a structuralist, Renou studied the different forms and genres of Sanskrit literature, including aesthetics and philosophy. Often he also discussed questions of religion, especially of Vedic ritual. He wrote several popular introductions and translated classical Sanskrit literature. He was one of the authors of the still-standard Sanskrit–French dictionary, and with Jean Filliozat he edited and to a large part wrote a massive introduction to classical Indian civilization (1949–1953). An important part of his large production was published as articles, often quite long, especially in the *Journal Asiatique*, many of which are now published in two collections (Renou, 1978, 1997).

Reported Speech: Pragmatic Aspects

W Bublitz and M Bednarek, Universität Augsburg, Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Every speech event involves a speaker, who usually commits him- or herself to its propositional, functional, and evaluative contents. But we can also refer to utterances of others and report what they said, wrote, meant, or thought. Reporting, a metalinguistic act, may be done through quoting (direct speech, *oratio recta*), paraphrasing (indirect speech, *oratio obliqua*) or in other ways and can relate to every aspect of an utterance. It is a powerful communicative strategy, whose different pragmatic functions are conventionalized (e.g., as a way of characterizing speakers rather than reproducing their utterances) or merely rhetorical (Roncador, 1988).

Multifunctionality of Reported Speech

Reported speech is multifunctional on several levels. On a very general level of establishing social order through talk, speakers report in order to display their understanding both of what occurred during a previous conversation and how it fits into the current communicative event. On a more pragmatic level, and with different degrees of authenticity and correspondence with the reported speech event, the reporter may simultaneously relate the propositional and functional content of the reported discourse, its contextual and situational environment, the way in which it was presented, and the speaker's (and/or the reporter's) emotional state and attitudinal stance.

Evaluative Functions

Evaluation is the central pragmatic function of reported speech. It can be related to its three main components: the source (who is responsible for the reported proposition), the reporting expression (referring to the source's saying), and the reported proposition(s) (what is reported).

The Source

Descriptions and qualifications of the source can be used strategically by speakers with the aim of influen-

Reported Speech: Pragmatic Aspects

W Bublitz and M Bednarek, Universität Augsburg, Augsburg, Germany

Every speech event involves a speaker, who usually commits him- or herself to its propositional, functional, and evaluative contents. But we can also refer to utterances of others and report what they said, wrote, meant, or thought. Reporting, a metalinguistic act, may be done through quoting (direct speech, *oratio recta*), paraphrasing (indirect speech, *oratio obliqua*) or in other ways and can relate to every aspect of an utterance. It is a powerful communicative strategy, whose different pragmatic functions are conventionalized (e.g., as a way of characterizing speakers rather than reproducing their utterances) or merely rhetorical (Roncador, 1988).

Multifunctionality of Reported Speech

Reported speech is multifunctional on several levels. On a very general level of establishing social order through talk, speakers report in order to display their understanding both of what occurred during a previous conversation and how it fits into the current communicative event. On a more pragmatic level, and with different degrees of authenticity and correspondence with the reported speech event, the reporter may simultaneously relate the propositional and functional content of the reported discourse, its contextual and situational environment, the way in which it was presented, and the speaker's (and/or the reporter's) emotional state and attitudinal stance.

Evaluative Functions

Evaluation is the central pragmatic function of reported speech. It can be related to its three main components: the source (who is responsible for the reported proposition), the reporting expression (referring to the source's saying), and the reported proposition(s) (what is reported).

The Source

Descriptions and qualifications of the source can be used strategically by speakers with the aim of influen-

cing the hearer's judgment of the reliability of what is reported.

Credentializing Giving high credibility to one's source (credentializing) is a means of giving high credibility to the reported proposition(s) (Stubbs, 1986; Fairclough, 1988; Hunston, 2000). In general, speakers pursuing this technique assume that the more reliable and credible (in other words, the more expert) the source is portrayed as, the more reliability will be attached to the content of the reported speech by the hearer. This technique also includes references to well-known, universally accepted authorities, as in *As Chomsky reminds us, "revolutionary new ideas appear infrequently"* (Haiman, 1989: 137). The qualification of the source may include further evaluation by means of attributive adjectives, as in *The noted educationalist A. H. Halsey has claimed that p* (Stubbs, 1986: 3).

Power and Solidarity Descriptions of sources can also be varied according to degrees of intimacy and distance. In studies on naming practices, the difference between referring to partners by first name (FN) and by title and last name (TLN) is related to the notions of intimacy and power (*see* **Power and Pragmatics**). Assuming that this practice can be transferred to ways of referring, reference to FN seeks to establish intimacy with and/or powerlessness of the referent, whereas reference to TLN establishes the referent as distant and/or powerful. Such references again involve the speaker's evaluation of the source, an evaluation that may be transferred to the evaluation of the reported proposition.

Labeling If sources are not explicitly identified by their names, labels are often employed to refer to them; such labels may be potentially evaluative. In newspapers, references to unspecified sources, experts, officials, professionals, etc., are extremely frequent. Labels like these are highly indeterminate in their referential meaning but imply more reliability than do other semantically vague labels (*a woman, a man*). The labels suggest that there was some well-founded reason for the journalist's consulting the reported speaker, namely that she or he is an authority on the matter. They imply the reliability of sources without having to identify them. Metonymy can be used to a similar effect, implying authority and/or reliability without mentioning named speakers (e.g., metonymic references to countries, institutions, etc.) (*see* **Metonymy**).

Paralinguistic Information Paralinguistic descriptions of the source's presumed emotional state, or of his or her manner of speaking may also have an impact on the hearer's evaluation of the source and the reliability of the reported proposition(s). Consider this example: *A downcast Mr. Trimble said that the evidence given to him by the commission was insufficient* (*Daily Telegraph* 11/22/03).

Explicit Evaluations Whereas the above-mentioned evaluations of sources are more or less implicit, explicit evaluations of the source may also be employed as a means of influencing the presumed reliability of reported propositions. Thus, labels with negative or positive connotations (*terrorists, fanatics, resistance fighters*), premodifying adjectives (*callous, racist, intelligent, cultivated*), or other explicit means of evaluation may be employed in order to credentialize or discredentialize sources.

The Reporting Expression

The other main way of evaluating the reliability of reported propositions is by virtue of the reporting expressions used. The most well-known are reporting verbs such as *say, state, claim*. But there are also reporting nouns (*disclosure, claim*), adjectives (*alleged, reported*) and prepositions (*according to*). Such expressions may communicate degrees of speaker agreement, as well as positive and negative evaluations.

Degrees of Speaker Agreement As has often been pointed out, reporting expressions may be neutral as to whether the speaker agrees with the reported proposition (*say, write*), positive/supporting (*X has rightly pointed out, proven, shown*) or negative/skeptical (*claim*, *pretend*) (Hunston, 2000; Thompson and Yiyun, 1991). By varying their use of such reporting expressions, speakers can again try to influence the hearers' perception of the reported proposition.

Positive and Negative Evaluations Like descriptions of sources, certain reporting expressions can also (more or less) explicitly trigger hearers' evaluations. Clayman (1990) has shown that the use of reporting verbs that refer to the discourse process invites hearers to make evaluative inferences about sources. Verbs such as *concede, admit*, for example, can imply that the source did not speak voluntarily and may prompt hearers to ask why; verbs such as *refuse, decline* indicate that the source did not in fact answer a question and may again prompt hearers to ask why. Similarly, illocutionary verbs that do not refer to the discourse process may be employed for purposes of evaluation. Whether someone *quips, jokes* and *promises* or *threatens*, *mocks* and *vows* can crucially influence hearers' interpretations. Combinations with

adverbs can enhance or neutralize negative reporting expressions (*he reluctantly admitted that* vs. *he frankly admitted that*). At the more explicit cline of evaluation, we can posit the use of reporting expressions that are almost unequivocally evaluated as negative (*boast, brag*). In making explicit the illocutionary force of speech acts, speakers thus signal their own evaluative stance toward the reported discourse and may predispose readers' interpretation (Fairclough, 1988). (Of course, even if the reporter faithfully reports the illocution of the speaker's utterance, the act is merely mentioned, not performed.) (*see* **Speech Acts; Mood, Clause Types, and Illocutionary Force**).

The Reported Proposition(s)

The last component of reported speech discussed is the reported proposition, with a focus on the different types of reported speech (i.e., direct speech, indirect speech, etc., and narrative reports of speech acts as distinguished by Leech and Short, 1981). Besides serving as résumés, abstracts, or conclusions of the reported speech, these types fulfill a gamut of pragmatic functions. Direct speech is generally regarded as highly reliable, because it purports to report the original speaker's actual choice of words, and hence functions pragmatically to lend reliability to the discourse (except when used as an expression of irony or "mocking mimicry"; Haiman, 1995). Indirect speech, on the other hand, does not claim to represent the original speaker's actual use of lexicogrammar, focusing on the ideational rather than the interpersonal meaning of reported propositions (*see* **Systemic Theory**). In spoken discourse, indirect speech is therefore often employed to clarify, to provide clear factual information to hearers (Mayes, 1990). In fiction, the "loss of . . . vivid, colloquial, partisan and engaged lexis" renders the narration "more 'neutral' and formal" (Toolan, 2001), resulting in greater distance between the reader and the characters. In free indirect speech the voices of the original speaker and the reporter are not as clearly demarcated as in direct speech: the two levels of discourse are merged (Fairclough, 1988) (*see* **Literary Pragmatics**). Consequently, free indirect speech (FID) is a powerful instrument in mystifying what could be called, with an allusion to Goffman, principalship (Fairclough, 1988) (*see* **Goffman, Erving (1922–1982)**). In fiction, FID is a characteristic of modernist stream-of-consciousness writing and serves a "strategy of . . . alignment, in words, values and perspective, of the narrator with a character" (Toolan, 2001), which may convey the speaker's irony or empathy (Toolan, 2001; Leech and Short, 1981). Narrative reports of speech acts, finally, may be regarded as the most evaluative, in that they consist wholly of the speaker's interpretation of an utterance or utterances she or he has heard. Since the speaker reports the occurrence of a speech act without mentioning its meaning, hearers have no possibility whatsoever to double-check the reporter's interpretation of the original speaker's words.

Social Functions

The choice of reported speech can be a means of establishing, maintaining, and securing social relations. By deciding what to report and how to report it, the reporter indicates different degrees of evaluative and social closeness or distance, of familiarity and formality, of politeness and respect (*see* **Politeness**). This may be achieved by verbal (including prosodic) and also nonverbal means (gestures, mimics, etc.), which originate with the reporter or else accompany the reported utterance (*see* **Gestures: Pragmatic Aspects**). (Rather than using *verba dicendi et sentiendi*, verbs related to 'body language' as in *She frowned/shrugged/smiled: '. . .'* can be used.) (*see* **Parentheticals**).

Textual Functions

Regarding textual functions, direct quotations can be used to dramatize and highlight important elements in a narrative (Mayes, 1990; Fairclough, 1988). In fiction, they are associated with a "scenic showing of pace, enhanced focus on the specificity and detail of an interaction" (Toolan, 2001), in short, "vivid and engaging" (Toolan, 2001) narration. Indirect speech seems less vivid and colorful, and narrative reports of speech acts appear to be often used when speakers do not want to transmit the actual words of the reported speaker, e.g., for purposes of abridging and summarizing.

Future Research

Many aspects of the pragmatics of reporting speech allow room for future research. A starting point could be the exploration of cross-cultural as well as genre-specific differences. Further research could investigate the connection between reporting speech and reporting thought as well as the relation between reported speech and notions such as evidentiality (Chafe and Nichols, 1986), commitment (Stubbs, 1986) and evaluation (Thompson and Ye, 1991).

Representation in Language and Mind

F Egan, Rutgers University, New Brunswick, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Languages are human artifacts used for a variety of purposes, most notably, communication. Mental states, such as beliefs, desires, intentions, hopes, and fears – the so-called 'propositional attitudes' – are internal states of organisms that are, typically, both effects of external conditions (and other mental states) and causes of behavior. Languages and states of mind are said to 'represent' – they can be about things other than themselves. They can even represent nonexistent states of affairs, such as, for example, Superman's working at the *Daily Planet*. One might wonder how it is possible for linguistic objects – utterances and inscriptions – and states of mind, both of which are physically realized, to represent, i.e., to have meaning or content. And one might wonder how a particular linguistic object or a particular mental state represents what it does. In virtue of what fact, for example, does a thinker's mental state mean *it will be raining soon*, rather than $2 + 2 = 4$? This tangle of issues is known as the 'problem of intentionality'.

The Relationship between Language and Thought

It is plausible that representation in language and representation in thought are related. A speaker's utterances typically express his or her thoughts. One can both think and say that it will be raining soon. Perhaps the limits of language are the limits of thought. Many theorists have found plausible the hypothesis that we can only think thoughts that can be expressed in public language. In any case, a theory of representation should explain how language and thought are related.

Several general strategies for explaining representation in language and mind are possible:

1. Mental representation might be construed as basic or fundamental, and the representational properties of utterances and inscriptions explained in terms of the mental states (beliefs, intentions, and

Representation in Language and Mind

F Egan, Rutgers University, New Brunswick, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Languages are human artifacts used for a variety of purposes, most notably, communication. Mental states, such as beliefs, desires, intentions, hopes, and fears – the so-called 'propositional attitudes' – are internal states of organisms that are, typically, both effects of external conditions (and other mental states) and causes of behavior. Languages and states of mind are said to 'represent' – they can be about things other than themselves. They can even represent nonexistent states of affairs, such as, for example, Superman's working at the *Daily Planet*. One might wonder how it is possible for linguistic objects – utterances and inscriptions – and states of mind, both of which are physically realized, to represent, i.e., to have meaning or content. And one might wonder how a particular linguistic object or a particular mental state represents what it does. In virtue of what fact, for example, does a thinker's mental state mean *it will be raining soon*, rather than $2 + 2 = 4$? This tangle of issues is known as the 'problem of intentionality'.

The Relationship between Language and Thought

It is plausible that representation in language and representation in thought are related. A speaker's utterances typically express his or her thoughts. One can both think and say that it will be raining soon. Perhaps the limits of language are the limits of thought. Many theorists have found plausible the hypothesis that we can only think thoughts that can be expressed in public language. In any case, a theory of representation should explain how language and thought are related.

Several general strategies for explaining representation in language and mind are possible:

1. Mental representation might be construed as basic or fundamental, and the representational properties of utterances and inscriptions explained in terms of the mental states (beliefs, intentions, and

so on) of speakers, hearers, writers, and readers. We shall call such theories 'mind-based' theories.

2. Linguistic meaning might be taken as basic and the meanings of mental states explained in terms of the thinker's linguistic capacities. We shall call these theories 'language-based' theories. They have the apparent consequence that nonhuman animals and prelinguistic humans do not have representational mental states – in other words, they do not literally have thoughts.
3. Neither thought nor language is construed as basic, though there may be some explanatory relations between aspects of each. We will call theories of this third type 'non-reductive' theories.

Mental Representation as Basic

The most popular theories of representation are mind-based, construing mental representation as basic and linguistic meaning as derivative of it. This explanatory strategy follows the program set out by Paul Grice in his seminal 1957 paper, 'Meaning'. Grice provides an analysis of a speaker's meaning something by an utterance on a particular occasion in terms of the speaker producing an utterance with a set of complex intentions to produce certain states of mind in hearers. Grice's analysis takes for granted the propositional attitudes of speakers and hearers. The question, then, is how these mental states acquire their meaning.

Some theorists of mind construe mental representation as itself language-like. Thought, they claim, takes place in an inner language or code (*see* **Mentalese**). Propositional attitudes, in this view, are relations to internal sentences. But whether or not the language-of-thought hypothesis is true, a theory of mental representation requires an account of how propositional attitudes acquire their meaning. And if the account is to serve as the basis for an explanation of representation in public language, then it must not presuppose public language meaning.

Mind-based theories are typically 'naturalistic': they aim to explain the intentionality (meaning, aboutness) of a subject's mental states in terms of non-semantic and non-intentional properties of those states. The intuition behind the naturalistic constraint is clear. An adequate account of intentionality – one that dissolves the air of ontological strangeness surrounding it – should explain it in terms compatible with the broader conception of nature provided by the natural sciences.

Information-Based Theories

Physical systems carry information about the external conditions that impinge on them. The number of rings in a tree's trunk reliably varies with the number of growing seasons; hence the tree's trunk carries information about, or represents, the age of the tree. Exploiting this general phenomenon, 'information-based' semantic theories take the meaning of a mental state or structure to be determined by the cause of its tokening in certain specifiable conditions. For example, a mental structure means *cat* if it is reliably caused by the presence of cats.

Mental states not only represent; they can occasionally **misrepresent**. Information-based theories have trouble accounting for misrepresentation. If a given mental structure is reliably caused by the presence of cats, then it is likely to be (reliably) caused by other things in less than optimal conditions, for example, by small dogs on a dark night. Since small dogs on a dark night are among the reliable causes of the structure, then, according to the theory, it means *cat or small dog on a dark night*. Rather than misrepresenting a small dog on a dark night as a cat, the mental state genuinely represents its disjunctive cause. Misrepresentation does not seem possible.

Proponents of information-based theories have attempted to solve the so-called 'error problem' by levying additional conditions on the circumstances in which a mental state's meaning is determined by the cause of its tokening. (See, for example, Fodor's 1990 account, which requires for a mental structure X to mean *cat* not only that it be reliably caused by cats, but also that if any non-cats cause X, then non-cat's causing X are **asymmetrically dependent** upon cats causing X; that is, non-cats would not cause X unless cats did, but not vice versa.) Whether these modifications handle the error problem without raising further difficulties is a matter of some dispute.

Teleological Theories

According to 'teleological' semantic theories, the meaning of a mental state or structure is determined by its biological function, i.e., that for which it was selected. (See Millikan, 1984, for the most developed proposal of this sort.) A variant of the error problem arises for theories that attempt to ground representation in biological function. A simple example makes the point. A frog will snap its sticky tongue at any fly moving in its vicinity. Some state of the frog's visual system represents the fly, but is the meaning of this state *fly*, *food*, or – given that the frog will react identically to any small dark object moving in its visual field – *small dark moving thing*? An appeal to the biological function of the frog's internal state will

not settle the issue, as there seems nothing to choose among describing the function of the state as *detecting flies,* as *detecting food* (given that flies are the only available food), or as *detecting small dark moving things* (given that almost all small dark moving things in the frog's vicinity are flies and hence food). A similar sort of indeterminacy is likely to plague efforts to establish the meaning of states of more complex systems, such as humans. The notion of biological function seems too coarse an instrument to determine representational content.

Conceptual Role Theories

'Conceptual role semantics' (CRS) is the most popular theory of mental representation. Versions of CRS have been developed and defended by philosophers, cognitive psychologists, and (under the guise of 'procedural semantics') computer scientists. (See Block, 1986, for a general defense of CRS.) According to CRS, a mental state means what it does in virtue of its causal role in the subject's mental life. What determines that a mental structure means *cats are furry* is the structure's role in perception, deductive and inductive inference, deliberation, action, and so on. Tokenings of the structure tend to be caused by the presence of furry cats and to cause one to conclude that if something is not furry then it is not a cat. The causal role of a structure meaning *dogs are needy* involves appropriate relations to dogs and instantiations of the property *neediness*.

A problem for CRS arises from the fact that a mental state's meaning is determined by the totality of its connections to perceptual stimuli, behavior, and other mental states. In this view, all of a subject's beliefs involving a concept contribute to its meaning. However, no two people have exactly the same beliefs involving any concept. If I believe that bats are scary but you do not, then, according to CRS, our 'bat-concepts' are different. Consequently, our beliefs involving our respective bat-concepts, even such core beliefs as each of us would express by the words 'Bats are mammals,' have different content. A consequence of the holistic determination of meaning is that no two subjects will share any concepts or any beliefs.

A proponent of CRS might try various maneuvers to mitigate the effects of holism. It is surely implausible to count every belief as contributing equally to the meaning of a concept. CRS needs some notion of **semantic importance** to distinguish the beliefs that contribute heavily to the meaning of associated concepts from those that do not. Whether such a notion can be spelled out without appeal to semantic or intentional notions – that is, without violating the naturalistic constraint – is an open question.

Constraints on a Theory of Mental Representation

In addition to accounting for the possibility of misrepresentation, and not leading to an unacceptable holism, a theory of mental representation must satisfy a 'cogency condition': the interpretation of a subject's mental states licensed by the theory must, by and large, make sense. The theory must not license an interpretation that makes the subject wildly irrational. The status of the cogency constraint is a matter of some controversy. Some philosophers (for example, Davidson (1984)) have thought it 'constitutive' of the intentional framework that thinkers are, by and large, rational. Others have thought only that, as a matter of empirical fact (perhaps because they are products of evolutionary adaptation), thinkers are typically rational.

An adequate theory of mental representation must also account for the fact that thought is fine-grained. The theory should explain how a thinker can believe that Cicero was a Roman orator but fail to believe that Tully was a Roman orator, even though "Cicero" and "Tully" are names for the same individual. This is known as 'Frege's problem'. Finally, as noted above, a theory should explain how thinkers can have thoughts about nonexistent objects or states of affairs, such as Superman's working at the *Daily Planet*.

Linguistic Representation as Basic

Norms-Based Theories

Language-based theories typically explain mental representation in terms of social practices governing overt speech (see, for example, Brandom, 1994). In this view, the social practices that confer meaning on utterances involve norms governing the correct use of certain expressions and the appropriate consequences of such uses. A given utterance-type justifies (that is, permits) certain other utterances and excludes certain others. A speaker who utters 'There is a dog' is committed to the assertion *There are some dogs* and to the denial of *There are no dogs* and is taken to be so committed by others. The relevant norms govern the actions of speakers and hearers, where action is not to be understood as presupposing intentional thought, but rather as behavior shaped by communal practices of conforming and censuring, what Brandom (1994) calls 'the game of giving and asking for reasons'. It is the communal practice of subjects' taking each others' performances as 'correct', 'incorrect', 'entitling', or 'excluding' other performances that confers meaning on these performances, and, derivatively, on the subjects' states of mind. The norms governing

these practices make intentionality of both speech and thought possible.

An account of this sort will succeed only if notions of 'correctness', 'entitlement', 'commitment', and so on, can themselves be understood in non-intentional and non-semantic terms. If we must presuppose that the relevant performances – both the utterances themselves and others' attitudes toward these utterances – are meaningful, if, for example, we must presuppose that these performances either involve the use of antecedently meaningful expressions or consist in actions produced with certain intentions in mind, then their meaningfulness does not reside in, or result from, the conforming and censuring practices themselves. The project fails if the social practices that supposedly confer meaning cannot be explained without presupposing that the performances governed by these practices have meaning. It is not obvious that this explanatory burden has been discharged.

A Non-Reductive Proposal

A non-reductive construal of the norms-based project is possible. One might see the task of articulating the structure of the norms governing overt speech as exposing how the intentionality of thought and the (public) norms governing overt speech are intimately connected. Such an account would aim to show that we cannot understand representation, in either language or thought, without a notion of inference, that is, without the idea of certain claims entitling or justifying others. (This idea is a cornerstone of the CRS developed by Wilfred Sellars.) On this construal, the project is an attempt to work out the interconnections between language and thought, without taking either as basic.

Defining the Issue

Perhaps the most important challenge for linguists who study language in its social context is to devise a methodology that allows them to record the everyday linguistic behavior of their informants, i.e., the casual, unmonitored speech that normally occurs outside of the sociolinguistic interview (Labov, 1966, 1972a). However, the typical sociolinguistic interview is an unnatural speech event – interviews are often set up in advance; many of the conversations are between fieldworkers and interviewees and not among the interviewees themselves; and in most cases the fieldworker, who is often a stranger to the interviewee and to the community itself, controls the topics and conversational turns. Moreover, the presence of an observer (a fieldworker with a recording device) creates an unnatural context for informal conversation, resulting in what Labov (1966) referred to as the 'observer's paradox' (the skewing of linguis-

these practices make intentionality of both speech and thought possible.

An account of this sort will succeed only if notions of 'correctness', 'entitlement', 'commitment', and so on, can themselves be understood in non-intentional and non-semantic terms. If we must presuppose that the relevant performances – both the utterances themselves and others' attitudes toward these utterances – are meaningful, if, for example, we must presuppose that these performances either involve the use of antecedently meaningful expressions or consist in actions produced with certain intentions in mind, then their meaningfulness does not reside in, or result from, the conforming and censuring practices themselves. The project fails if the social practices that supposedly confer meaning cannot be explained without presupposing that the performances governed by these practices have meaning. It is not obvious that this explanatory burden has been discharged.

A Non-Reductive Proposal

A non-reductive construal of the norms-based project is possible. One might see the task of articulating the structure of the norms governing overt speech as exposing how the intentionality of thought and the (public) norms governing overt speech are intimately connected. Such an account would aim to show that we cannot understand representation, in either language or thought, without a notion of inference, that is, without the idea of certain claims entitling or justifying others. (This idea is a cornerstone of the CRS developed by Wilfred Sellars.) On this construal, the project is an attempt to work out the interconnections between language and thought, without taking either as basic.

Defining the Issue

Perhaps the most important challenge for linguists who study language in its social context is to devise a methodology that allows them to record the everyday linguistic behavior of their informants, i.e., the casual, unmonitored speech that normally occurs outside of the sociolinguistic interview (Labov, 1966, 1972a). However, the typical sociolinguistic interview is an unnatural speech event – interviews are often set up in advance; many of the conversations are between fieldworkers and interviewees and not among the interviewees themselves; and in most cases the fieldworker, who is often a stranger to the interviewee and to the community itself, controls the topics and conversational turns. Moreover, the presence of an observer (a fieldworker with a recording device) creates an unnatural context for informal conversation, resulting in what Labov (1966) referred to as the 'observer's paradox' (the skewing of linguis-

tic behavior toward norms of correctness as a result of the mere presence of a fieldworker). As a result, the interview itself creates a situation where obtaining the most casual speech styles is difficult at best.

Approaches to Fieldwork

Community Fieldworkers

Over the past four decades sociolinguists have designed varying approaches to fieldwork in an effort to mitigate the effects of the observer's paradox. Because the social and ethnic barriers between fieldworkers and informants are often cited as key factors that could affect stylistic variation, one popular approach has been to use fieldworkers who are either community members, ethnically similar, or in the best scenario, both. Labov (1972b) was one of the first researchers to use same-race community members as fieldworkers to record the use of African American Vernacular English (AAVE) by adolescents in Harlem. Wolfram (1974) in Mississippi, Wolfram, and Christian (1976) in Appalachia, and most recently Rickford and McNair-Knox (1994) in East Palo Alto have all used similar fieldwork strategies.

While differences in data from community and non-community members have not been systematically investigated (although recent work by Bell, 2001 touches on this issue), Rickford and McNair-Knox (1994) have tested the hypothesis of same-race fieldworkers through a quantitative comparison of the use of five African American Vernacular English (AAVE) features by an urban African American teenager in interviews conducted by both an African American and an Anglo fieldworker. They show that the teenager's use of AAVE features is significantly higher in the interview conducted by the African American fieldworker, and conclude that the race of the interviewer accounts for this discrepancy.

Research by Cukor-Avila and Bailey (2001), however, suggests that other factors, including interview context and familiarity of the interview participants, might have influenced Rickford and McNair-Knox's results. For example, when the African American fieldworker recorded her interview her teenage daughter, who went to the same school as the interviewee, accompanied her. These two young women functioned as a kind of peer group during the interview. In contrast, the Anglo fieldworker, who had not previously met the teenager, was the only person present during the interview. Cukor-Avila and Bailey's data from parallel interviews with rural Texas speakers show that when interview context and familiarity of the interview participants remain constant, there is no significant difference in the use of AAVE features for two female speakers (one teenage and one elderly) when interviewed by African American community members and when interviewed by an Anglo fieldworker who had spent several years in the community. In fact, the only statistically significant difference they found was in the use of invariant *be* by the teenage girl who used it more frequently with the Anglo fieldworker. Their results suggest that any effects the race of the interviewer might typically have on vernacular use can be minimized when fieldworkers have spent time in the community and are familiar with community norms (see discussion below).

Peer Group Recordings

Another strategy frequently used by fieldworkers to reduce the effects of the observer's paradox is to record subjects in peer group contexts. Labov *et al.* (1968) used this strategy in conjunction with a community fieldworker in interviews conducted with African Americans and Puerto Ricans in New York City. Blom and Gumperz (1986), Cheshire (1982), Eckert (1989), Wolfram and Schilling-Estes (1996), and Childs and Mallinson (2004) have all systematically incorporated interviews with peer groups into their fieldwork. They used groups that 'self-select,' and, like Milroy (1987a,b), interviewed these groups in places where they naturally congregate. Fieldwork in Philadelphia (Labov, 1984) extended the community fieldworker approach with the addition of a set of question modules designed to control the topics of conversation. Fieldworkers can often manipulate topics in order to direct the conversation to subjects that lead to more spontaneous speech. This strategy has also been used to create conversational contexts for interviewees to use targeted forms, e.g., *be*+V+*ing,* as in *She be tellin' me what to do an' I don't like it,* for AAVE speakers (Bailey and Maynor, 1987, 1989). (For a criticism of this strategy, see Wolfram, 1987.)

Ethnographic Fieldwork

Sociolinguists have also incorporated the techniques of participant observation used by ethnographers (cf. Geertz, 1973; Spradley, 1980; Schieffelin, 1979; Eckert, 1989) into their fieldwork. In an ethnographic approach fieldworkers:

- Invest a substantial amount of time in a community. They delve deeply into a community by visiting there frequently over an extended period of time (or by living there), and by participating in everyday community activities.
- Document and record the everyday language of a community in its cultural context.

- Capture actual linguistic interaction rather than surrogates for interaction.
- Continually evaluate observations of and information gathered from community members, thereby allowing the linguistic data to be interpreted within the context of the cultural behavior and knowledge of the community.

Participant-observation may be one of the best ways to reduce the effects of the observer's paradox and to document the linguistic interactions of community members with each other, rather than with fieldworkers. This is because the more time fieldworkers spend in a community interacting with residents on a daily basis, the more they will be trusted and the less they will be perceived as outsiders. Both Baugh (1983) and Dayton (1996) have made effective use of participant-observation in their studies of AAVE speakers in Los Angeles (Baugh) and Philadelphia (Dayton); however, they typically did not tape their observations. Thus, their data are limited to the observations they could make on the spot and record on note cards shortly thereafter. As is shown in the examples below, informal conversations can be taped within the context of ethnographic fieldwork.

An Ethno-Linguistic Approach to Fieldwork

What follows is an overview of an approach to fieldwork that is both ethnographic and linguistic. This approach was developed during the course of a longitudinal study in the rural Texas community of Springville (the name of the community and the names of informants mentioned in the examples below are all pseudonyms), designed to document linguistic variation and change in rural Southern speech over time (see Cukor-Avila, 1995; Cukor-Avila and Bailey, 1995; and Bailey and Cukor-Avila, forthcoming for a complete discussion of the history of Springville and the methodology of the Springville project). The approach applies insights from ethnography to sociolinguistic fieldwork and demonstrates how sociolinguists can shift the focus of study to the community itself, consequently allowing the recording of people as they normally interact with each other on a daily basis. More specifically, this approach records people in normal sites of linguistic interaction with one another rather than with fieldworkers, talking about topics that they normally talk about and involved in the kinds of speech events they normally participate in.

The Community of Springville

Springville is a contemporary relic of the plantation agriculture that developed during tenancy and was typical of the post-Civil War South; in fact, many of the community's approximately 150 residents either worked as tenant farmers or are their descendents. Most of the land and almost all of the houses are owned by one woman, who also owns the only store in town. She maintains financial control over much of the community – many residents borrow money from her and purchase items from the store on credit, reconciling their tabs on the first of the month after she cashes their government checks.

The significance of the store for the residents of Springville is not unique. The country store in the post-Civil War South played a major part in shaping the lives of rural people and served as the foundation for the economy of the New South (Ayers, 1992).

The role that the store plays in Springville was the most important consideration in the development of the field methods used throughout the project. The store is not only the principal place of business in the community, but more importantly, it is also the primary community hangout. It provides a meeting place for people to gossip, watch soap operas, eat lunch, read their mail, or simply just pass the time. This is especially true on days when rainy weather prevents people from working in the fields.

The Springville Project

The Springville Project relied on three techniques to ameliorate the effects of the observer's paradox:

1. Multiple interviews with informants.
2. Interviews in which informants interacted with each other rather than or in addition to fieldworkers.
3. The use of community fieldworkers.

Most fieldworkers know that subsequent interviews with informants usually produce more unguarded conversations and speech more like that used when no fieldworker is present. The Springville Project applied this observation as an organizing principle: people were interviewed as many times as possible, not only over a period of years (for longitudinal purposes), but also within the same year (to increase the familiarity between interviewer and interviewee). What made this approach possible, of course, was the extensive amount of time that fieldworkers Patricia Cukor-Avila and Guy Bailey spent in the community. Cukor-Avila's daily visits to Springville over a two-month period and frequent return visits by both Cukor-Avila and Bailey over the years have provided

many opportunities for additional interviews. The effects of subsequent interviews can be dramatic, as Texts 1 and 2 below demonstrate.

Multiple Interviews Over Time

Text 1 was recorded July 12, 1988, and is the first interview Cukor-Avila conducted with Vanessa, an African American female born in 1961.

Text 1

CA: What time do you, what time does the store open? Like what time do you work from?
V: I come at eight an' get off at four thirty.
CA: Uh huh. So what do your kids do while they're at home? What do they do during the daytime when they're not in school?
V: Well they jus' got outta summer school an' they jus', they haven' been doin' too much of anything but layin' aroun' watchin' TV an' fussin' an' fightin' an' callin' over here for me. [laughs]
CA: Oh yeah you can hear 'em I bet.
V: Yeah.
CA: So what kinda' stuff do they fight over? Now lemme see now, tell me who's the oldest? The boy or the girl?
V: The girl.
CA: An' then the next one is . . .
V: Is the boy an' the girl.
CA: Uh huh, so who fights with who?
V: It be, it be mostly the baby fightin' with the oldes' girl. She jealous. She always want things to go her way. An' when it don't she wanna fight 'em. So it's the baby always wanna fight.
CA: Uh huh. So what about the boy? What does he play, referee?
V: Yeah, he do. He uh, he's, he's like the man of the house. He watch over them an' when they get to fussin' too much he get on 'em. He keeps 'em in order.

Recorded shortly after Cukor-Avila first met Vanessa, the text reflects classic interview style and follows a simple question/answer format, with Vanessa answering all of the questions but providing little elaboration. While the interview (and even this short text) includes a number of vernacular features, no one would argue that it reflects the everyday speech that Vanessa uses when no fieldworker is present. A second interview recorded a week later demonstrates the advantages of follow-up interviews. Vanessa's responses are much more elaborate, and she provides an unsolicited narrative on a rather personal topic. It is more like the everyday speech that the fieldworkers had observed Vanessa using with other Springville residents.

The next passage, recorded nine years later, (March 13, 1997) after many visits with Vanessa, is less like an interview and more like a conversation between two friends. The interviewee feels free to change and initiate topics, and she assumes that the fieldworker has a repository of shared knowledge regarding the characters in the narrative. Both Vanessa's language and her linguistic interactions are much like what she had been observed using on numerous occasions with friends and family in Springville.

Text 2

V: They some nuts. I can't stan' 'em. I had to go over there an', an', an' uh with my gun an' trip out on them about her.
CA: What? What happened?
V: R called me one night an' she say, "Aunt V," she say, "I'm tired of them runnin' over P."
Say it was C tried to jump on her firs' an' then the sisters an' then the mama was cussin' her out. I told R about it that night an' P was over here. I say, "This is it." I say, "I'm fit to go over here an' 'front these people an' let them know that she got somebody that love her an' if they keep messin' with her I will shoot 'em."
So I got my gun. They say, "We ain' gonna let you go by yourself."
So B, R, an' P went with me. I went over there an' knocked, I knocked on the door. An' they say, "Who is it?" I say, "It's Vanessa." "Come in." I say, "No I'm not comin' in. Yall come outside." So she opened the door. I say, "Lookie here. I'm tired of yall messin' with my child. If, if you don't want her here or she's not welcome around here I'll take her home with me right now."
I said, "But yall not gonna keep runnin' over her an' keep fightin' her an' keep cussin' her because I will shoot you. An' I'm not gonna play with yall. An' the nex' time that I hafta come out here by my child I'm comin' an' I'm gon be ready to do somethin' to all of yall." Ohhh they were scared. And uh, an' I was sayin', "If you don't like what I'm sayin' come on out here an' we can jus', we can do whatever we gotta do tonight an' get it over with."
Ohhh they were scared Patricia. They closed the door on me an' I asked P. I said, "P. do you wanna come home?" [mimics] "No." I say, "You so crazy." I said, "But you gonna cry an' you gonna wish you hada came home with me." An' sure enough in a month time she came home. I say, "I'm not gonna put up no more with yall's junk." An' everytime they see me they still scared of me.
I wasn' playin' with 'em. I was tired of it. An', an' I, I guess they kep' doin' her wrong

because you know they, I guess they felt like that nobody, you know, she didn' have nobody to care about her an' stuff. I wen' an' let them know that's my child an' you're not gonna keep doin' her wrong. Uh huh.

Peer Group Interviews

As useful as multiple interviews with informants are for ameliorating the observer's paradox, they still involve an interviewer talking to an interviewee. Linguists have frequently used group interviews as a mechanism for creating situations in which informants talk to one another. Group interviews have been used most often with teenagers and adolescents (cf. Labov, 1968, 1972b), but the Springville Project extended this mechanism to adults and used it as an organizing principle for fieldwork. Moreover, the priority of the Springville Project was recording naturally occurring groups rather than groups brought together by the fieldworkers specifically for an interview. Multiple interviews, an ethnolinguistic approach to fieldwork, and the frequent presence of the fieldworkers in the community were crucial in identifying and recording these naturally occurring groups.

Text 3, which is from an interview with two African American males born in 1913, is an example of a recording with a naturally occurring peer group, while the circumstances that led to the interview illustrate how interviews such as these come about. Cukor-Avila first met Wallace in July 1988 while she was interviewing another Springville resident. During the course of that interview Wallace, who was selling vegetables, drove up, was introduced to Cukor-Avila, and joined in the conversation. Cukor-Avila and Bailey subsequently interviewed Wallace individually on five occasions over the next three weeks. Wallace then invited them to his house for a home-cooked barbecue dinner; unbeknownst to them, he had also invited his best friend, Reggie. Text 3 is from the two-hour interview recorded on that occasion (August 17, 1988). As this excerpt about Hurricane Carla suggests, the interview consists primarily of conversation between Wallace and Reggie – of two friends talking to one another rather than to the fieldworkers (CA, GB).

Text 3

R: Yeah. I was jus' gettin' outta work here when it was ol' Carla.
W: Boy it was rough down here, it was rough.
R: Sure I mean.
W: All cars.
R: You oughta seen Galveston.
W: All cars, all cars all off in the ditch.
R: You oughta seed Galveston.
CA: There probably wasn't much of it huh.
R: That great big ol' steel, them brick, stone houses, rock houses, brick homes, an' some of them buildings out there with that steel in it that wide. It jus' double it up like that.
W: I went, I went up here to look at this here in Waco that time R was heading up there . . . .
R: I bet you I went up there twice.
W: The man had said, "Shoot ain' no way in the world." I said, "Well what you think about that?" Man them railroads, rail, it jus' bent 'em double. An' that rail, that bridge that go across the river – it tore it up.
R: That man told me in Waco – I went up there twice up there – an' them guys told me they was sittin' where, jus' like this house sittin' on concrete blocks or cedar block, had long left there. An' he said they frigidaires was in the air like paper.
W: Well I was sittin' over there on the railroad. I was workin' on the railroad up there. I had a sister over there. It blowed all her stuff away. An' then see they wouldn' let us come in there, over there, 'cause they had done got all them soldiers from, from Killeen up there. They wouldn' let us come there. I couldn' get no further to the river. The further they let us go. They wouldn' let us go over there.
GB: That was in Waco. There was a big tornado up there?
W: That was in Waco.
R: Yeah man. Went right down the street, an' when it got to the courthouse it just parted.

Addressing the Observer's Paradox

Group interviews such as in Text 3 provide significant amounts of speech between Springville residents, but the interviewers nevertheless remain part of the interview context. The ultimate goal of sociolinguistic fieldwork, however, is to diminish the role of the interviewer and allow informants to interact with each other, as they would normally do if the fieldworker were not present. An important component of Labov's model of stylistic variation (i.e., the consequences of the amount of attention paid to speech) was the creation of contexts within the casual interview situation that would elicit spontaneous speech, a style used in excited, emotionally charged conversations when informants would be the least likely to pay attention to their speech (Labov, 1972a). These contexts include remarks to

Figure 1 Interlocutor roles (adapted from Bell A (1984). 'Language style as audience design.' *Language in Society 13,* 145–204 with permission of Cambridge University Press).

the interviewer outside of the formal interview itself; speech to third parties who happen to intrude on the interview; speech not in direct response to questions (i.e., digressions); discussions of childhood games and rhymes; and responses to danger of death questions.

Labov's techniques for eliciting spontaneous speech styles were a key advance in sociolinguistic field methods. Subsequent variation research, however, has suggested that not all of these strategies successfully create contexts for the most casual speech. Milroy (1987a), for example, suggests that fieldworkers have no way of ensuring the intrusion of third parties or even of systematically getting comments outside of the formal interview context. Moreover, the use of danger of death questions is often inappropriate – such was the case for her informants in Belfast.

An alternative conception of style defines stylistic variation as a direct consequence of speakers' linguistic accommodation to the people who are listening to them – of a shift toward the interlocutors' speech. As a result, stylistic or intraspeaker variation should be analyzed in light of the speech of a speaker's audience since it is the speech of the audience that provides both the impetus for variation in the first place and also the target for accommodation. Bell's audience design theory produces a model that can be perceived of as a series of concentric circles, as in Figure 1. The further away in audience role interlocutors are, the less effect they will have on intraspeaker variation and thus on the degree of accommodation.

Bell's approach to style provides a scheme for understanding how the observer's paradox works. As Table 1 shows, the concepts from audience design can be adapted to estimate the effect that a fieldworker might have on intraspeaker variation (or style shifting). In individual interviews, the staple of sociolinguistic methodology, the fieldworker is the addressee; in addition, the fieldworker is often an outsider to the community and frequently a member of a different social class or ethnic group. In peer group interviews the role of the fieldworker shifts from addressee to auditor and the peers become the addressees as group members primarily interact with each other and not with the fieldworker. This is clearly shown in Text 3 above.

Site Studies

The third interview situation, site studies (see Text 4 below), provides a context where the fieldworker is a participant-observer (cf. Geertz, 1973; Spradley, 1980) rather than a 'ratified participant' (Bell, 1984, 2001) at community gathering places. Moreover, the fieldworker becomes an overhearer to interactions where peers are the primary addressees and auditors (see Table 1). Site studies represent a strategy for ameliorating the observer's paradox because the focus of the fieldwork is not on the speech of individual informants, but on the speech used at strategic sites of linguistic interaction over a given period of time (Cukor-Avila and Bailey, 1995). Many of the recordings during the initial phase of the Springville fieldwork in 1988–1989 were done at the Springville Store, the main gathering place in the village, where Cukor-Avila was hanging out on a daily basis. Over time she became friends with people from the community and gained their trust, and soon the interviews became closely intertwined with the day-to-day business of the store and began to include a wide range of unsolicited linguistic interactions, including teasing, arguments, jokes, business transactions, and the routine conversations that make up much of Springville's linguistic activity. Cukor-Avila was able to record these conversations between community members because they arose naturally while she was talking to people in the store.

Text 4, which is an excerpt from a site study recorded at the Springville Store in August 1988, provides examples of this type of interaction. These texts also illustrate three main features of site studies: (1) the rapid and natural ways that interlocutor roles change, (2) the rapid and natural ways that topics change without input from the fieldworker, and (3) the occurrence of embedded and parallel conversations (shown in italics in the transcripts).

Table 1 Typical audience structure of different types of fieldwork

Audience design	*Addressee*	*Auditor*	*Overhearer*	*Eavesdropper*

Text 4

R: Me an' my girlfrien' walkin' one night, walkin' . . . [RB and S overlap]

RB: YThat's the same one you an' M. saw ain' it?

S: Yeah that's the one they say an' then M. tol' me he ain' tellin' the truth. Same way I tell him firs'. [SR walks up],. Mr. Stan!

RB: Howdy Mr. Stan.

SR: What's, what's goin' on, the riff?

S: The riff. Nothin' but the riff. Get a sodie water. O.K., uh, we'll be down here all day I 'magine. [laughs]

R: [continues his story] An' uh, we were walkin' along there talkin'. Then cross the railroad track. All at once grabbed me a stick. "Hey boy, what you standin' on me for?" "Don' you see that man you walkin' into?" She mean it. She could see him.

S: But she seen him?

R: Uh huh.

S: Man. Wooo. Now I knew I was seein' things which I thought was a ghost. But when you come to realize that it, it don' be nothin' but a bush [L. overlaps]

L: That you see in the road.

S: . . . or, or somethin' that, that, you know, that you haven' seen.

R: I know, I know some guy – that be years ago – about six young guys, you talkin' about young men. Well they had a meetin' that day in the church at night. There was this crazy German in the church. Along in them days you didn' have no uh, lightnin' paper. You had to use newspaper. People goin' to church an' they'd throw the paper down side of the road an' it blowed up aroun' in some piles that was about that high. An' them guys walkin' to the church that night an' the wind's blowin'. An' that paper come an' blowed up aroun' that stuff. They looked at [unintelligible]. Everyone of 'em had a gun. They emptied that, them guns in that paper an' BOOM! [S laughs and overlaps R] Newspaper blowed up aroun' in piles an' stuff . . .

S: An' that's all it was?

R: Uh huh.

S: You see that, that's what I'm talkin' about here. A person eyes can fool you.

R: Oh yeah.

S: Oh, they can fool you.

R: But I ain' gonna let mine fool me.

S: [to P.] Hey lover, where you goin'?

P: To wash my hands.

S: [to FW] You didn' know that she was a lover did you? [laughs]

R: My eyes ain' never fooled me but one time. That time I tell you I, that man come down on me.

S: Uh huh.

R: Well it didn' fool me then. An' I've no doubt what it was.

S: Well it, it was a real man?

R: No. It wasn' nothin' but a large snake standin' up in the fiel'. M shot it for me walkin' jus' like it was [S laughs/overlaps]

S: Hey. Well one night I did the same thing. I run from a, a stump. It started off, started off about this high. It was humped over like that. I run till I jus' run myself to death. An' the nex' day I went back by there. I said, "I'm gonna see what was that." An' it was jus' a ol' tree they had cut off high.

A: Tell the reason why you were runnin'.

S: Shit. Girl I was runnin'. See I was doin' somethin' I don' have no business to know with. You know that! [everyone laughs] Thought I had got caught an' I was runnin' like the devil. An' the nex' day I come back by there. I said, "You know a man'd kill hisself for nothin' wouldn' he." 'Cause if somein' got in my way I'd run over it. An' you know you can run a long ways when you're scared. You can move an' never get tired.

A: Specially when you somewheres where you ain' s'posed to be.

S: Yeah I was where I wasn' s'posed to be. [laughs] I didn' do it no more neither. I got scared. That scared me good! I said, "Ohh." I ain' gonna tell yall what I said but I sure was cussin' boy. I said, "Hot dog got caught!"

In Text 4, Cukor-Avila is an auditor and an overhearer; S directly addresses her in an aside. Moreover, because Cukor-Avila is not an interviewer but a participant in a community activity, she does not control the floor (i.e., does not determine who speaks), nor does she control the topics. The natural, everyday flow of linguistic interaction that typically takes place at the store develops. There are also two embedded conversations within this excerpt. The first one occurs when R attempts to begin his story but pauses while RB and S have a short conversation in which others at the store are not ratified participants. The second one occurs when S flirts with P, who passes by on her way to the bathroom. (Flirting and teasing are common speech acts in the store; this episode is typical).

While embedded conversations such as these are typical of the everyday linguistic interaction at the store, parallel conversations among different sets of interlocutors are just as common. In these situations, one group of interlocutors carries on a conversation independently of, and sometimes even unaware of, another group that is carrying on a conversation. Oftentimes lulls in one group's conversation allow members to overhear part of another group's conversation and occasionally to make comments across groups. Moreover, people occasionally move back and forth between groups, there is fluid shifting of topics and interlocutor roles, and unsolicited narratives occur.

Conclusion

Site studies allow fieldworkers to become overhearers rather than addressees, and they create contexts in which speech outside of the interview situation becomes the norm rather than the exception. In addition, site studies provide a unique cultural and linguistic window on a community by allowing fieldworkers access to witness, participate in, and record speech events typically absent from sociolinguistic interviews. As Text 4 demonstrates, the focus on a strategic site of linguistic interaction, rather than on individuals or groups of people, makes it possible for fieldworkers to record the natural linguistic interactions of community members with each other, rather than with the fieldworkers.

While site studies certainly do not eliminate the observer's paradox, they can substantially ameliorate it. Because the sites themselves are a natural part of the community and the recordings made at the sites are of natural speech, these recordings, coupled with recordings from individual, peer group, and community fieldworkers (preferably over time), can provide sociolinguists with a broad range of data for both qualitative and quantitative linguistic analysis.

Respect Vocabulary in Austronesian

K Cook, Hawaii Pacific University, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

In a number of Austronesian languages, speakers replace everyday vocabulary with a special set of words in order to show respect for addressees and/or referents. This phenomenon fits under the broader rubric of honorifics; the term 'honorifics', however, includes not only the use of respect vocabulary, but also morphosyntactic adjustments to speech, including special pronouns, affixes, and verb forms (*see* **Honorifics**). Furthermore, the term is traditionally used in descriptions of non-Austronesian languages of East and South Asia, e.g., Japanese, Korean, Tibetan, and Thai. A well-known (and well-studied) exception, however, is Javanese, an Austronesian language spoken in Indonesia that has an elaborate honorific system (Errington, 1988; Geertz, 1960; Uhlenbeck, 1970). Vocabulary substitution is part of the Javanese honorific system; for example, the everyday word for 'rice' *sega*, is replaced by the word *sekul* in the more formal speech styles. Similarly, the respect word *tindak* 'go out' replaces the non-honorific verbs *mangkat, késah*, and *lunga*, which also mean 'go out' (Errington, 1988).

Within the Austronesian family, respect vocabulary has been reported in Polynesia (Samoan, Tonga, East Futuna, Wallisian, and previously Hawaiian, Tahitian, and, with a reduced lexicon, Niue), Micronesia (Namoluk, Ponapean (Pohnpeian), and formerly Kusaie (Kosraean), Marshallese, and Palauan), Indonesia (Alune, Bali, Javanese, Madura, Nuaulu (North and South), Sangihé (Sangir), Sasak, Sunda, and Tetun Terik (Eastern Tetun)), the Loyalty Islands (Dehu and Nengone), Fiji and Rotuma, and Madagascar (the southern dialects of Malagasy) (Blixon, 1969; Florey and Bolton, 1997; Fox, 2005; Grimes and Maryott, 1994; Nothofer, 2000; van Klinken, 1999; and Verguin, 1957).

Samoan serves as an example of how respect vocabulary is employed in a Polynesian language. In Samoan, about 450 respect words (called *'upu fa'aaloalo*) are substituted for everyday terms when the speaker addresses or refers to chiefs or orators (Milner, 1961). For instance, the ordinary word *fale* 'house' is replaced by *maota* when referring to the house of a chief, whereas it is substituted with *laoa*

In a number of Austronesian languages, speakers replace everyday vocabulary with a special set of words in order to show respect for addressees and/or referents. This phenomenon fits under the broader rubric of honorifics; the term 'honorifics', however, includes not only the use of respect vocabulary, but also morphosyntactic adjustments to speech, including special pronouns, affixes, and verb forms (*see* **Honorifics**). Furthermore, the term is traditionally used in descriptions of non-Austronesian languages of East and South Asia, e.g., Japanese, Korean, Tibetan, and Thai. A well-known (and well-studied) exception, however, is Javanese, an Austronesian language spoken in Indonesia that has an elaborate honorific system (Errington, 1988; Geertz, 1960; Uhlenbeck, 1970). Vocabulary substitution is part of the Javanese honorific system; for example, the everyday word for 'rice' *sega*, is replaced by the word *sekul* in the more formal speech styles. Similarly, the respect word *tindak* 'go out' replaces the non-honorific verbs *mangkat, késah*, and *lunga*, which also mean 'go out' (Errington, 1988).

Within the Austronesian family, respect vocabulary has been reported in Polynesia (Samoan, Tonga, East Futuna, Wallisian, and previously Hawaiian, Tahitian, and, with a reduced lexicon, Niue), Micronesia (Namoluk, Ponapean (Pohnpeian), and formerly Kusaie (Kosraean), Marshallese, and Palauan), Indonesia (Alune, Bali, Javanese, Madura, Nuaulu (North and South), Sangihé (Sangir), Sasak, Sunda, and Tetun Terik (Eastern Tetun)), the Loyalty Islands (Dehu and Nengone), Fiji and Rotuma, and Madagascar (the southern dialects of Malagasy) (Blixon, 1969; Florey and Bolton, 1997; Fox, 2005; Grimes and Maryott, 1994; Nothofer, 2000; van Klinken, 1999; and Verguin, 1957).

Samoan serves as an example of how respect vocabulary is employed in a Polynesian language. In Samoan, about 450 respect words (called *'upu fa'aaloalo*) are substituted for everyday terms when the speaker addresses or refers to chiefs or orators (Milner, 1961). For instance, the ordinary word *fale* 'house' is replaced by *maota* when referring to the house of a chief, whereas it is substituted with *laoa*

when speaking of the house of an orator. At times, word choice also depends on the rank of the chief or orator. For example, *sāunoa, fetalai,* and *vāgana* replace the ordinary verb *tautala* 'speak' for chiefs, orators, and high orators, respectively. In some cases, one respect word substitutes for two or three related common terms. For instance, the respect word *fofoga* replaces *gutu* 'mouth', *isu* 'nose', and *mata* 'eye'. Sometimes the respect word also has a surprisingly different everyday meaning, e.g., the term *'ele'ele* is both the respect word for 'blood' and the ordinary term for 'dirt'. Words borrowed from English into Samoan (e.g., *naifi* 'knife') tend to be considered ordinary (not respect) terms. Samoan also has formulaic expressions that indicate respect. For example, the expression used when a high chief dies is *'ua pa'ū le māsina* 'the moon has fallen' (Milner, 1961; Schultz, 1980).

Going beyond Milner's (1961) analysis of the Samoan vocabulary of respect, Duranti (1992) showed that factors other than the status of the addressee/referent trigger the use of respect words. For example, respect words are more likely to be employed (1) during (rather than before or after) a *fono*, i.e., a formal village meeting attended by chiefs and orators, (2) when speaking as a chief or orator rather than as an ordinary individual, (3) when referring to an individual as a chief or orator rather than as a sibling, for example, and (4) when coercing the addressee to behave in a chiefly manner, i.e., with generosity and/or restrained demeanor. As Duranti pointed out, by using respect words in these ways, the speaker is creating context by means of respect terms and expressions rather than merely reacting to elements in the given context (see also Uhlenbeck, 1970).

Tonga, a Polynesian language closely related to Samoan, employs two degrees of respect vocabulary, one for nobles and the other for the king or God. For example, the common word for 'eat', which is *kai*, is replaced by *'ilo* when addressing or talking about nobles, and by *taumafa* when addressing or referring to the king or God. Likewise, the respect words *pekia* and *hala* substitute for the everyday word *mate* 'die' when addressing or referring, respectively, to nobles and the king or God (Churchward, 1953). As these and the preceding examples suggest, respect words often refer to items, states, or activities that are part of or very close to the revered individual, e.g., body parts, homes, family members, names, desires, health, and bodily activities. Respect words mitigate the disrespect that would be shown to someone held in high regard by talking about such personal matters.

Individuals, no matter how high their rank, use ordinary (and not respect) words when they refer to themselves or their possessions. In addition, some languages have self-abasement or humbling forms. For example, the Samoan first-person singular pronoun *'ita* (as opposed to the ordinary *a'u*) reflects self-disparagement on the part of the speaker. Of related interest, Keating (1997, 1998, 2000) showed that Ponapean (Micronesian) has not only self-abasing forms, but also other-lowering forms.

Lexical replacement of respect words for everyday vocabulary also occurs in the context of addressing in-laws in the northern islands of Vanuatu. Alex Francois (personal communication) reported that speakers of the Austronesian language Mwotlap (formerly called Motlav), which is spoken in the Banks Group, employ three strategies when addressing or referring to their in-laws: they use pronouns or kinship terms rather than personal names; they employ dual rather than singular pronouns; and they make use of an honorific register called *hohole map* 'talk respectfully' (etymologically, 'talk heavy'), which involves replacements for 100–200 lexical items in particular, but also some morphosyntactic adjustments. Similar 'avoidance languages' exist in the Australian aboriginal languages Dyirbal (Dixon, 1972) and Guguyimidjir (Haviland, 1979a,b), which have been referred to as 'mother-in-law language' and 'brother-in-law language', respectively. The respect shown in these avoidance languages, rather than being for a person of high status, is for the in-law relative, with whom there is a ban, by taboo, against having a close relation. (*see* **Honorifics**, for more on the Australian avoidance languages, as well as humbling forms, and Javanese honorifics.)

This accomplished jurist and linguist pioneered the study of Hebrew at the turn of the 16th century in the Christian West and helped establish a philological approach to language and texts within European universities. Inspired by the Italian humanists Marsilio Ficino and Giovanni Pico della Mirandola, Reuchlin was drawn to Hebrew by an interest in Jewish esoteric mysticism, the Kabbalah. He further determined that Hebrew literacy would be advantageous to Christian theology because God had revealed himself in that language in the Old Testament. He also suggested that if Christians knew the Hebrew texts better, Jews could be more effectively converted. He composed several works to encourage Hebrew literacy among Christian scholars: a Hebrew lexicon and grammar, *De rudimentis hebraicis* (Pfortzheim, 1506); the Hebrew text of the Seven Penitential Psalms with Latin translation and commentary, *In septem psalmos poenitentiales* (Tübingen, 1512); and a handbook on accents and spelling, *De accentibus et orthographia linguae hebraicae* (Hagenau, 1518).

Reuchlin's interest in the Kabbalah and the Talmud, a collection of Jewish laws and traditions from Late Antiquity and the Early Middle Ages, drew him into one of the most celebrated controversies of the period. The so-called Reuchlin Affair had implications for the study of Hebrew as well as for the humanist curricular reform at the universities and for the Lutheran Reformation. In 1509 a baptized Jew, Johann Pfefferkorn, obtained the permission of the emperor to confiscate and destroy Jewish books for being offensive to Christianity and a hindrance to the conversion of Jews. A wary archbishop of Mainz,

This accomplished jurist and linguist pioneered the study of Hebrew at the turn of the 16th century in the Christian West and helped establish a philological approach to language and texts within European universities. Inspired by the Italian humanists Marsilio Ficino and Giovanni Pico della Mirandola, Reuchlin was drawn to Hebrew by an interest in Jewish esoteric mysticism, the Kabbalah. He further determined that Hebrew literacy would be advantageous to Christian theology because God had revealed himself in that language in the Old Testament. He also suggested that if Christians knew the Hebrew texts better, Jews could be more effectively converted. He composed several works to encourage Hebrew literacy among Christian scholars: a Hebrew lexicon and grammar, *De rudimentis hebraicis* (Pfortzheim, 1506); the Hebrew text of the Seven Penitential Psalms with Latin translation and commentary, *In septem psalmos poenitentiales* (Tübingen, 1512); and a handbook on accents and spelling, *De accentibus et orthographia linguae hebraicae* (Hagenau, 1518).

Reuchlin's interest in the Kabbalah and the Talmud, a collection of Jewish laws and traditions from Late Antiquity and the Early Middle Ages, drew him into one of the most celebrated controversies of the period. The so-called Reuchlin Affair had implications for the study of Hebrew as well as for the humanist curricular reform at the universities and for the Lutheran Reformation. In 1509 a baptized Jew, Johann Pfefferkorn, obtained the permission of the emperor to confiscate and destroy Jewish books for being offensive to Christianity and a hindrance to the conversion of Jews. A wary archbishop of Mainz,

the leading prelate in Germany at the time, consulted with several leading theologians and jurists, including Reuchlin, who condemned the indiscriminate destruction of these books, arguing that very few of the Jewish texts in question were heretical and that the emperor was legally obliged to protect Jewish life and property. The emperor consequently rescinded his order. But Pfefferkorn opened what became a lengthy exchange of polemical letters with Reuchlin, accusing him of Judaizing. Reuchlin responded, accusing Pfefferkorn of boorish stupidity. Reuchlin further belittled scholastic theologians who claimed to work from the Bible without facility in Hebrew. After some 10 years of mutual denunciations, Reuchlin was convicted of Judaizing and nominally fined. Nonetheless, he had through this very process become one of the most celebrated intellectuals in Europe. Afterwards, he moved to Tübingen, where he taught Greek and Hebrew at the university and took the Augustinian cowl. He died in 1522.

The significance of the Reuchlin affair and its implications for other tensions in German society cannot be overstated. The dispute itself sheds light on a distinction concerning the tolerance of Christian intellectuals for Judaism that is fine but crucial for the period: on the one hand, Reuchlin condemned the ignorant anti-Semitism of Pfefferkorn and his allies that would lead to the indiscriminate destruction of valuable, ancient scholarship. On the other hand, Reuchlin's opposition to the destruction of these books was not born out of any love for Judaism and the Jews *per se*, but rather out of a sectarian Christian admiration for philological learnedness typical of and central to Renaissance humanism north of the Alps. This controversy became the neuralgic point for two additional controversies that were to prove shattering to German society: first, the Reuchlin affair became a rallying point for German humanists and scholastic theologians in their battle against each other over control of German education, and second, Luther and his circle saw the Reuchlin affair to be a foreshadow of their own battles against the dominant scholastic model of theology practiced within the German church and academy.

The French Overseas Department of Réunion consists of an island in the southern Indian Ocean, between Madagascar and Mauritius. Réunion, together with the neighboring islands of Mauritius and Rodrigues, was known to early travelers and the islands were recorded by the Portuguese in 1512. They came under the influence of the French, and in 1764, Réunion became a French colony. Following the Napoleonic wars, Britain assumed control over Mauritius, Rodrigues, and the Seychelles, while Réunion remained French. During the mid-19th century, the island became an important stop-over port on the

route to India, as well as an important sugar producer, but the opening of the Suez canal in 1870, and competition on the sugar market from Caribbean islands, led to economic decline. Shortly after World War II, Réunion became a French Overseas Department, and is as such a member of the European Union. In 2004, Réunion also joined the Common Market for Eastern and Southern Africa.

Being a part of France, the official language of Réunion is French. However, the most widely spoken language is Réunion Creole French, which is used by more than 90% of the 766 000 strong population. Urban dialects of Réunion Creole are closer to French, while popular dialects show more influence from African, in particular Bantu languages. Archaic forms of Réunion Creole are spoken in the mountainous interior of the islands, where early settlers had to move when their land was taken by larger sugar plantations, while the basilect is spoken by Indian, African, and mixed speakers in the coastal lowlands.

Like Mauritius, Réunion is home to a significant Indian community, speaking Tamil (120 000 speakers) and Gujarati. Other languages on the island include Chinese, Malagasy, and Comorian.

Reversing Language Shift

S Romaine, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Language shift is symptomatic of much larger-scale social processes which have brought about the global village phenomenon, affecting people everywhere, even in the remotest regions of the Amazon. Some linguists estimate that as many as 60% to 90% of the world's 6800-some languages may be at risk of extinction within the next 100 years. Language shift may be thought of as a loss of speakers and domains of use, both of which are critical to the survival of a language. The possibility of impending shift appears when a language once used throughout a community for everything becomes restricted in use as another language intrudes on its territory. Usage declines in domains where the language was once secure, e.g., in churches, the workplace, schools, and, most importantly, the home, as growing numbers of parents fail to transmit the language to their children. Fluency in the language increases with age, as younger generations prefer to speak another (usually the dominant societal) language.

Reversing Language Shift

To understand how to reverse language shift, we must first understand how languages are maintained. Language shift and death occur as a response to pressures of various types (social, cultural, economic, and even military) on a community. The term 'reversing language shift' (RLS) was proposed by Fishman (1991) in order to provide theoretical foundations of assistance to communities wishing to counteract forces leading to shift. The achievement of intergenerational transmission in the context of stable diglossia, where each language has its own domains of use, constitutes the heart of Fishman's conception of RLS.

Using Fishman's (1991) schema of X to refer to the language undergoing shift and Y to refer to the language replacing X, we can represent the process of shift in this formula: $X \rightarrow Xy \rightarrow XY \rightarrow xY \rightarrow Y$. We can represent RLS as its mirror image, a kind of role reversal, where X reclaims the domains it has lost to Y: $Y \rightarrow Yx \rightarrow YX \rightarrow (yX) \rightarrow (X)$.

XY and YX represent stable diglossia. X and Y appear in upper case to indicate that diglossia is stable; each language has its own set of functions and space without threatening the other. Lower case (Xy, xY, Yx, yX) symbolizes that x or y is dominated by the other language. Bilingualism without diglossia tends to be transitional and the predicted outcome of such situations is language shift (Fishman, 1967: 36). From Fishman's perspective, the future of minority languages would be problematic without sharp functional compartmentalization of codes and without the most stubborn maintenance of voluntary boundaries between the dominant and minority language speakers and their cultures.

The last two stages of RLS are in parentheses to indicate that RLS does not necessarily mean going back to a stage where X reclaims the majority of domains (i.e., yX). Nor is it the case that all X-men

Reversing Language Shift

S Romaine, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Language shift is symptomatic of much larger-scale social processes which have brought about the global village phenomenon, affecting people everywhere, even in the remotest regions of the Amazon. Some linguists estimate that as many as 60% to 90% of the world's 6800-some languages may be at risk of extinction within the next 100 years. Language shift may be thought of as a loss of speakers and domains of use, both of which are critical to the survival of a language. The possibility of impending shift appears when a language once used throughout a community for everything becomes restricted in use as another language intrudes on its territory. Usage declines in domains where the language was once secure, e.g., in churches, the workplace, schools, and, most importantly, the home, as growing numbers of parents fail to transmit the language to their children. Fluency in the language increases with age, as younger generations prefer to speak another (usually the dominant societal) language.

Reversing Language Shift

To understand how to reverse language shift, we must first understand how languages are maintained. Language shift and death occur as a response to pressures of various types (social, cultural, economic, and even military) on a community. The term 'reversing language shift' (RLS) was proposed by Fishman (1991) in order to provide theoretical foundations of assistance to communities wishing to counteract forces leading to shift. The achievement of intergenerational transmission in the context of stable diglossia, where each language has its own domains of use, constitutes the heart of Fishman's conception of RLS.

Using Fishman's (1991) schema of X to refer to the language undergoing shift and Y to refer to the language replacing X, we can represent the process of shift in this formula: $X \rightarrow Xy \rightarrow XY \rightarrow xY \rightarrow Y$. We can represent RLS as its mirror image, a kind of role reversal, where X reclaims the domains it has lost to Y: $Y \rightarrow Yx \rightarrow YX \rightarrow (yX) \rightarrow (X)$.

XY and YX represent stable diglossia. X and Y appear in upper case to indicate that diglossia is stable; each language has its own set of functions and space without threatening the other. Lower case (Xy, xY, Yx, yX) symbolizes that x or y is dominated by the other language. Bilingualism without diglossia tends to be transitional and the predicted outcome of such situations is language shift (Fishman, 1967: 36). From Fishman's perspective, the future of minority languages would be problematic without sharp functional compartmentalization of codes and without the most stubborn maintenance of voluntary boundaries between the dominant and minority language speakers and their cultures.

The last two stages of RLS are in parentheses to indicate that RLS does not necessarily mean going back to a stage where X reclaims the majority of domains (i.e., yX). Nor is it the case that all X-men

Stage 8	Most vestigial Xish users are socially isolated and Xish needs to be reassembled from their mouths and memories and taught to demographically unconcentrated adults
Stage 7	Most Xish users are a socially integrated and ethnolinguistically active population but are beyond child-bearing age
Stage 6	The attainment of intergenerational informal oralcy and its demographic concentration and institutional reinforcement
Stage 5	Xish literacy in the home, school and community, but without taking on extra-communal reinforcement of such literacy
Stage 4	Xish in lower education that meets the requirements of compulsory education laws
Stage 3	Use of Xish in the lower work sphere (outside the Xish neighborhood/community) involving interaction between Xmen and Ymen
Stage 2	Xish in lower governmental services and mass media but not in higher spheres of either
Stage 1	Some use of Xish in higher level educational, occupational and media efforts (but without the additional safety provided by political independence)

Figure 1 GIDS (Graded Intergenerational Disruption Scale) (adapted from Fishman, 1991: 88–109).

(to use Fishman's terminology) will come to speak X as their native language, as they did in the past. It most certainly does not entail returning to monolingualism in X.

Figure 1 summarizes the eight-point GIDS (graded intergenerational disruption scale) introduced by Fishman (1991) to characterize the extent to which a particular language (X) is endangered by assessing the extent to which transmission has been disrupted. It is intended as a heuristic device to assist communities in targeting their efforts to specific activities needed at each point of the scale. This follows from Fishman's view that language maintenance is not "a global 'total language' task," but rather a "functionally specific process which must be tackled on well-chosen, functionally specific grounds" (Fishman, 1991: 65).

GIDS can be further divided into two sets of four stages. The first set, comprising stages 8–5, is characterized as "RLS on the 'weak side': in pursuit of diglossia," and the second set, comprising stages 4–1, is termed "RLS on the strong side, or transcending diglossia in search of increased power-sharing" (Fishman, 1991: 396, 401). RLS on the weak side aims primarily to establish intergenerational transmission, whereas RLS on the strong side aims to introduce the minority language into various institutions. Stage 6 is the crux of RLS because only intergenerational transmission secures maintenance. Stages 8–6 are labor intensive rather than cost intensive in that they depend on the ability of individuals and communities rather than external agencies such as governments or education systems.

One of the most frequent mistakes activists make is to attempt to reverse the diglossic hierarchy by promoting the minority language in the domains now dominated by the majority language. What often results from active intervention to reverse language shift is a reversal of domain distribution in X and Y, with a decrease in the use of X at home and in private domains, and an increase in its use in public, formal domains such as government, education, etc. The net result is that X is forced to compete with Y in virtually all domains. Fishman (1991: 54–55) compared the distribution of Basque and Spanish in 1957 and 1987, noting that over this 30-year period there was a decrease in the use of Basque at home and in private domains, while there was a slight increase in the use of Basque in public, formal domains such as government, education, etc. In Wales too, where Welsh has been introduced in public domains where it used to be excluded, e.g., public administration and education, its previous dominance in other critical domains such as the home, and even the chapel in some areas, has been weakened. The family is no longer the main agency of language reproduction. It has been largely replaced in this role by education. More children are learning Basque through the education system than are learning it at home as a native language. Among the youngest sectors of the population, those who have learned Basque as a second language already outnumber native Basque speakers. The same is true of many other cases. The maintenance of more or less stable rates of bilingualism over recent decades in Ireland has been due more to the capacity of the schools to produce competent bilinguals than to

the capacity of the bilingual community to reproduce itself (Ó Riagáin, 1997).

Other Paradigms for Reversing Language Shift

Fishman's conception of RLS is narrowly focused in its specific aims at the same time as it is broad in scope. Its focus is narrow in the sense that everything that does not lead to the restoration of intergeneration transmission is merely camouflaged failure and amounts to biding time (Fishman, 1991: 86, 399). Its scope is broad in that RLS involves nothing short of cultural reconstruction and community building through the threatened language (Fishman, 1991: 17). As Fishman (2001: 452) put it more recently, "RLS is concerned with the recovery, recreating and retention of a **complete way of life**, including both non-linguistic as well as linguistic features."

Nettle and Romaine (2000: 79, 179) observed that the first causes in language loss are not themselves linguistic. Where language use changes, there is an underlying social upheaval which may have environmental, economic, or political causes. The preservation of a language in its fullest sense ultimately entails the maintenance of the group who speaks it, and therefore the arguments in favor of doing something to reverse language death are ultimately about preserving and sustaining viable communities.

Criticisms of the stable diglossia model as the key to RLS have noted that insofar as the diglossia that Fishman is so concerned to stabilize is in effect a symptom of the unequal balance of power between languages, diglossia is something to be overcome rather than to be attained. It may be more realistic to recognize King's (2001: 26) distinction between RLS and language revitalization, which can be understood as not necessarily attempting to bring the language back to former patterns of familial use, but rather to bring the language forward to new users and uses. In doing so, however, we must not deceive ourselves that the efforts directed at the latter will restore intergenerational transmission. There may be an increase in users and uses of language without intergenerational transmission. Spolsky (2003: 554–555) proposed that in addressing the question of success or failure of Maori efforts we need to 'desynonymize' a number of terms often used interchangeably. He prefers the term 'regeneration' for activities that increase the status and salience of a language, and reserves 'revitalization' for the restoration of intergenerational transmission. His perspective on Maori sees it not as an instance of language loss followed by attempts to reverse language shift, but as the continuation of a long process of negotiation of accommodation between Maori and English. Indigenous voices which have begun to make themselves heard in this arena are often angered at the suggestion that their language is dead, or that it is endangered and may die, and they resent such pronouncements and predictions from linguists, however well intentioned (see Quinn, 2001).

Fishman (2001: 461) himself warned of the dangers of arriving at conclusions by overemphasizing a limited pool of historical experience. He observed that "most RLS theories and efforts are byproducts of European indigenous minority problems." Linguistic theory, like most scientific disciplines, is grounded in Western models rather than in indigenous epistemologies. He acknowledges the need for a general and more inclusive RLS theory. The ideological bias of his own model of RLS privileges intergenerational transmission, a fact that is not unconnected with the special status traditionally accorded within linguistic theory to native speakers.

Rhaeto Romance

G Darms, University of Fribourg, Fribourg, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Since Th. Gartner (1883), the term 'Rhaeto-Romance' has been associated with the Romansh dialect of Graubünden, Switzerland; the Ladin dialects of the Dolomitic Alps in South Tyrol, Italy; and the Friulian dialects around Udine, spoken at the northern and eastern border of the Italian speaking area, at the frontier of the German and Slovene areas. Before Gartner's time, these three dialectal territories had been linked, though under another name (Ascoli, 1873) or with no name yet (Schneller, 1870). The term 'Rhaeto-Romance,' however, had already been used before Gartner to describe the Romansh dialects of Graubünden (Diefenbach, 1831) and in 1938 this term even became the constitutional designation for these dialects in Switzerland. The term therefore is not used with consistency.

The language territory of Romansh is part of the canton Graubünden, an administrative subdivision of Switzerland. The first coherent written evidence is a testimony of a witness from a record written in Latin in 1389. The first longer text was written in 1527, but it has survived only in later copies. In the 16th and 17th centuries, different books of exclusively confessional content were published. They were the starting point for four different regional written standards: the two Engadine written standards Puter and Vallader as well as two different Surselvan variants, a catholic one and a protestant one, that were united at the beginning of the 20th century. In the meantime, however, another regional standard had emerged: Surmeiran. To these standards, Sutselvan was added in the first half of the 20th century. This fragmentation, along with the topographic conditions that hardly allowed for direct contact between the different regions, was the reason why the dialects developed separately, so that a certain acclimatization is actually necessary to assure the supra-regional understanding.

In the constitution of Graubünden, Romansh was put on an equal footing with German and Italian, the two other cantonal languages of Graubünden, already in 1880. It was, however, never extensively used as a language of administration, especially as the lack of a uniform written standard for the Romansh meant that in each case, two regional written standards had to be used for administration. In the schools of the language territory, in which Romansh is usually the only language of instruction until the third form, all five regional written standards are used, though Sutselvan is used in only one school. In 1938, Romansh was granted the status of a national language, but not of an official language. There have also been attempts to create a uniform written standard for the entire Romansh territory, e.g., in 1864 the *Romonsch fusionau,* which failed however, and more recently the *Rumantsch Grischun* (1982), which is accepted on federal as well as cantonal level as a language of administration.

In the 2000 census, the number of speakers who indicated Romansh as main language amounted to only 27 038 in Graubünden and 35 095 in Switzerland; there are 40 168 in the canton (60 651 in Switzerland) who still use the language in at least some domains (family, school, etc.). Although the number of Romansh speakers has remained surprisingly stable since the first comparable census in 1880, its portion of the population of the canton of Graubünden has decreased from 40% to 14% (main language) and 21% (domain language). Even in some territories previously Romansch dominant, the Romansh speakers have nowadays become a minority. Sutselva and Upper Engadine are in fact falling out of use.

The language territory of Dolomitic Ladin is nowadays divided among three Italian provinces: Bolzano (Gadera Valley, Gardena), Trentino (Fassa), and Belluno (Ampezzo, Livinallongo). The first known text dates from 1631, but until the end of the 19th century very little was written in Ladin and only a few books were published. Towards the end of the 19th century, Ladin was used more frequently in writing, but between 1915 and 1948 the efforts for the written use of Ladin were restrained for political reasons. Fragmentation occurred between 1923 and 1927 under fascist rule and was intended to weaken Ladin, accompanied by other measures to suppress this language. In 1948, Ladin was given special status in Bolzano and Trentino. The Ladins of Ampezzo and Livinallongo (Belluno) did not receive a similar Special Statute.

Rhaeto Romance

Since Th. Gartner (1883), the term 'Rhaeto-Romance' has been associated with the Romansh dialect of Graubünden, Switzerland; the Ladin dialects of the Dolomitic Alps in South Tyrol, Italy; and the Friulian dialects around Udine, spoken at the northern and eastern border of the Italian speaking area, at the frontier of the German and Slovene areas. Before Gartner's time, these three dialectal territories had been linked, though under another name (Ascoli, 1873) or with no name yet (Schneller, 1870). The term 'Rhaeto-Romance,' however, had already been used before Gartner to describe the Romansh dialects of Graubünden (Diefenbach, 1831) and in 1938 this term even became the constitutional designation for these dialects in Switzerland. The term therefore is not used with consistency.

The language territory of Romansh is part of the canton Graubünden, an administrative subdivision of Switzerland. The first coherent written evidence is a testimony of a witness from a record written in Latin in 1389. The first longer text was written in 1527, but it has survived only in later copies. In the 16th and 17th centuries, different books of exclusively confessional content were published. They were the starting point for four different regional written standards: the two Engadine written standards Puter and Vallader as well as two different Surselvan variants, a catholic one and a protestant one, that were united at the beginning of the 20th century. In the meantime, however, another regional standard had emerged: Surmeiran. To these standards, Sutselvan was added in the first half of the 20th century. This fragmentation, along with the topographic conditions that hardly allowed for direct contact between the different regions, was the reason why the dialects developed separately, so that a certain acclimatization is actually necessary to assure the supra-regional understanding.

In the constitution of Graubünden, Romansh was put on an equal footing with German and Italian, the two other cantonal languages of Graubünden, already in 1880. It was, however, never extensively used as a language of administration, especially as the lack of a uniform written standard for the Romansh meant that in each case, two regional written standards had to be used for administration. In the schools of the language territory, in which Romansh is usually the only language of instruction until the third form, all five regional written standards are used, though Sutselvan is used in only one school. In 1938, Romansh was granted the status of a national language, but not of an official language. There have also been attempts to create a uniform written standard for the entire Romansh territory, e.g., in 1864 the *Romonsch fusionau,* which failed however, and more recently the *Rumantsch Grischun* (1982), which is accepted on federal as well as cantonal level as a language of administration.

In the 2000 census, the number of speakers who indicated Romansh as main language amounted to only 27 038 in Graubünden and 35 095 in Switzerland; there are 40 168 in the canton (60 651 in Switzerland) who still use the language in at least some domains (family, school, etc.). Although the number of Romansh speakers has remained surprisingly stable since the first comparable census in 1880, its portion of the population of the canton of Graubünden has decreased from 40% to 14% (main language) and 21% (domain language). Even in some territories previously Romansch dominant, the Romansh speakers have nowadays become a minority. Sutselva and Upper Engadine are in fact falling out of use.

The language territory of Dolomitic Ladin is nowadays divided among three Italian provinces: Bolzano (Gadera Valley, Gardena), Trentino (Fassa), and Belluno (Ampezzo, Livinallongo). The first known text dates from 1631, but until the end of the 19th century very little was written in Ladin and only a few books were published. Towards the end of the 19th century, Ladin was used more frequently in writing, but between 1915 and 1948 the efforts for the written use of Ladin were restrained for political reasons. Fragmentation occurred between 1923 and 1927 under fascist rule and was intended to weaken Ladin, accompanied by other measures to suppress this language. In 1948, Ladin was given special status in Bolzano and Trentino. The Ladins of Ampezzo and Livinallongo (Belluno) did not receive a similar Special Statute.

In connection with the introduction of Ladin in schools and partly also in the administration, different regional written standards were developed, first for the Gardena Valley (Gardenese). This written standard was first also used in the Gadera Valley, which later (1970) went its own way (Badiot). Somewhat later, a regional written standard was also developed in the Fassa Valley (Fassan). It is taught in school too, though only the basics. Also for Ampezzo (Ampezzan) and Livinallongo (Fodom), regional written standards were developed. There use is restricted, as in these regions Ladin is not taught in schools. Since 1988, there have been efforts to develop a uniform written standard for all Ladin speakers, the *Ladin Dolomitan*. The dialectal differences are not as big as in Swiss Romansh; the territory of Dolomitic Ladin is much more compact than the Swiss Romansh territory, although topographic barriers also make contacts difficult.

There's no reliable data on the number of speakers of Ladin. They are included in official statistics only in the province Bolzano; in the other territories they still count as speakers of Italian. In the province Bolzano, 18 736 inhabitants consider themselves as Ladins and in eight communities, the Ladins still have large majorities of between 82% and 97% (2001). With regard to the population of the province of South Tyrol, however, this amount represents only slightly more than 4%. According to estimates, the Ladins are also a majority in the other communities in their territory, with exception of Ampezzo. It is estimated that the total of Ladin speakers amounts to 27 000–30 000.

The Comelico and Cadorine dialects are sometimes associated with Ladin. Recent dialectometrical research, however, does not seem to confirm this affiliation.

The language area of Friulian is situated in the northeast of Italy, in the provinces Pordenone, Udine, and Gorizia, and reaches from Forni Avoltri to just outside Trieste. In the west, the borders of the linguistic frontier to the Venetian dialects are fluid; a transitional zone can be discerned. Already in 1336, the language appears in a coherent text and in the second half of the 14th century, the texts become more frequent. The two oldest poems also date from the 14th century. In Friuli, the art of poetry starts at the beginning of the 16th century and already in one of the first sonnets, *In laude de lenghe furlane* 'In praise of the Friulian language' by Girolamo Sini, writing in Friulian is a topic. This first great age of Friulian literature came to a halt under the influence of Venetian; from 1420 to 1797 Friuli was under Venetian rule. In the 19th century, however, the literary activity was taken up again and has continued until today. Contrary to Swiss Romansh, this reinterest has not led to the development of regional written standards, although Friulian dialectal regions exist: western Friulian, central Friulian, also called east-central Friulian, and Carnic Friulian in the north. Since 1963, Friuli is part of the autonomous region Friuli-Venezia Giulia.

The dialectal differences in Friulian are, however, smaller than in Dolomitic Ladin and in Swiss Romansh, and the mutual understanding assured at all time. There are, however, certain tendencies to use one supra-regional variety in literature, namely the central Friulian of the region around Udine, also called 'common Friulian.' These tendencies, however, are not significant and have been contradicted by opposing tendencies reconsidering the use of the local dialect also as literary language. Since 1985 systematic efforts have been made to create a uniform Friulian written standard. These became particularly urgent as efforts were made to use Friulian in school, on a voluntary basis though, which was rendered possible by the minority law in 1999. Based on this use of the language in a new domain an official orthography was sanctioned the same year and seems to be well on the way.

The number of speakers of Friulian can once again only be based on estimates, as it has not been recorded statistically either. In the actual language territory, it has been estimated at about 600 000, to which 300 000 from outside the territory should be added. The total of speakers of Friulian in the region Friuli-Venezia Giulia would thus amount to about 50%. In any case, Friulian certainly has a sufficiently large number of speakers not to be considered an endangered language. The actual use of the language, however, still seems to be limited to a great extent to the family. It is also to be considered that Friulian has to compete with another Romance language, Italian, contrary to Romansh in Graubünden and Ladin in the Dolomitic Alps, which live in competition with German.

The summing up of these three linguistic areas under the term 'Rhaeto-Romance,' which happened

in the second part of the 19th century, was mainly based on some phonetical (e.g., maintenance of *Cl-*) and morphological (e.g., maintenance of *−s* in the plural and in the 2.sg.pl.) particularities that mainly distinguish these linguistic areas from the adjacent northern Italian dialects. This differentiation was questioned beginning in 1912 (Salvioni) in connection with the changing political situation and the rise of the national states, first and foremost by Italian scholars. The scientific part of the discussion was mainly about the importance of the common features of the three speech communities. These common features were then contrasted with similar features in the neighboring Italian dialects. In the 1980s, thanks to the newly developing dialectometry, this discussion has been resumed on a scientifically more solid basis. Electronic data processing of enormous amounts of material allowed comparison, and it became possible to show that the Rhaeto-Romance linguistic area, based on the maps of the *Dialect Atlas of Italy and Southern Switzerland* (AIS). At the time of the recording of the AIS, northern Italian dialects clearly differed from each other on the one side, but on the other side, they presented significantly more common features (Goebl, 1984). Friulian, however, differed less with its surrounding northern Italian dialects than Swiss Romansh or Dolomitic Ladin. The results of the AIS have recently been confirmed and refined with data, collected since 1985, of the *Atlant linguistich dl ladin dolomitich y di dialec vejins* (ALD). The detailed interpretation of these results, however, is pending.

In any case, since the 17th century there are no direct frontiers between these three linguistic areas anymore. It is to be noted, however, that all three language areas use their own regional written standards, even though these can by far not cover all written domains, which strongly distinguishes them from the bordering northern Italian dialect regions.

Rhetoric, Classical

C Ilie, Örebro University, Örebro, Sweden

© 2006 Elsevier Ltd. All rights reserved.

The notion of 'classical rhetoric' is normally associated with the Western tradition of a structured system of teaching public speaking and writing skills that was developed in ancient Greece; taught in Roman, medieval, Renaissance, and early modern schools; and, with certain variations, is still in use today (Golden *et al*., 1993/1976; Enos, 1996; Bizzell and Herzberg, 2001). According to Corbett and Connors (1999), the classical tradition of rhetoric extends from the fifth century B.C.E. down to the close of the eighteenth century C.E. The changing roles that rhetoric has played in politics, social life, and education may account for the emergence of several rhetorical systems and schools of thought.

We are now experiencing a revival of rhetoric, that restores the dignity it had under Aristotle, for whom rhetoric, poetry, philosophy, and science were indissolubly linked. Rhetorical theory provides, in interde-

in the second part of the 19th century, was mainly based on some phonetical (e.g., maintenance of *Cl-*) and morphological (e.g., maintenance of *−s* in the plural and in the 2.sg.pl.) particularities that mainly distinguish these linguistic areas from the adjacent northern Italian dialects. Rhetoric, Classical

C Ilie, Örebro University, Örebro, Sweden

© 2006 Elsevier Ltd. All rights reserved.

The notion of 'classical rhetoric' is normally associated with the Western tradition of a structured system of teaching public speaking and writing skills that was developed in ancient Greece; taught in Roman, medieval, Renaissance, and early modern schools; and, with certain variations, is still in use today (Golden *et al*., 1993/1976; Enos, 1996; Bizzell and Herzberg, 2001). According to Corbett and Connors (1999), the classical tradition of rhetoric extends from the fifth century B.C.E. down to the close of the eighteenth century C.E. The changing roles that rhetoric has played in politics, social life, and education may account for the emergence of several rhetorical systems and schools of thought.

We are now experiencing a revival of rhetoric, that restores the dignity it had under Aristotle, for whom rhetoric, poetry, philosophy, and science were indissolubly linked. Rhetorical theory provides, in interde-

pendence with other social structures and means of communication, elaborate ways to reconstruct reality and to participate in structuring socio-political relations (Booth, 2001/1974; Kennedy, 1999/1980; Covino and Jolliffe, 1995; Herrick, 2001). A major point of departure in exploring rhetoric is the rhetorical role played by language as a conceptualizing and persuasive tool, as a means of communication, and as a bearer of values (Dumarsais, 1825/1730; Fontanier, 1968/1830; Perelman and Olbrechts-Tyteca, 1969; Groupe μ, 1976/1970; Barthes, 1988).

The Origins of Rhetoric

Rhetoric developed under Greek democracy in the fifth century B.C.E. and has since been used as the systematic practice of persuasive communication strategies in crucial areas of social life, such as public affairs, civil disputes, law courts, and education. A major prerequisite for the development of rhetoric was the establishment of constitutional democracy in Greece, which required the participation of ordinary citizens in the decision-making process to a degree not existing in other literate cultures.

According to standard scholarly accounts (Clark, 1957; Bryant, 1968; Vickers, 1988; Enos, 1993; Enos, 1995; Kennedy, 1994; Kennedy, 1999/1980; Murphy and Katula, 1995; Foss *et al.*, 2001), the art of rhetoric originated in Syracuse with Corax of Sicily (around 467 B.C.E.), who was the teacher of Tisias, a fellow Sicilian. It is assumed that Corax and/or Tisias authored the first *technē* (rhetorical handbook). Although judicial rhetoric developed in Syracuse, it was Athens that became the leading center for displays of oratory. In Athenian courtrooms, the procedure was for each side (plaintiffs and defendants) to be allotted a given amount of time to present their own case. The speaker had to demonstrate credibility, use persuasive arguments, and keep the jury interested.

A competing approach to the technical teaching of rhetoric was introduced during the mid- to late fifth century B.C.E. through the practices of the Older Sophists (Jarratt, 1991; Mailloux, 1995; Poulakos, 1995; Grimaldi, 1996; Vitanza, 1997). The Sophists (the best known of whom are Protagoras, Gorgias, and Isocrates) were mostly non-Athenian Greeks who could not participate directly in the politics of Athens and who acted as itinerant orators and teachers of rhetoric. Their status as outsiders raised distrust, and their approach was discredited for a number of reasons. First of all, they tended to see all language use as rhetorical and rhetoric as knowledge building, whereas different communities and traditions might see things differently. Second, their students were supposed to learn rhetoric primarily by imitating exemplary speeches, whereas Greeks traditionally thought that such virtues could not be taught. Third, as several scholars of classical rhetoric (Cole, 1991; Schiappa, 1991; Schiappa, 1999; Robb, 1994; Cassin, 1995) have pointed out, the fifth century B.C.E. was a period when Greece underwent a transition from a predominantly oral culture to an increasingly literate culture, which must certainly have left its imprint on the heated intellectual debates concerning the role of rhetoric.

In his book *Rhetoric*, Plato's student Aristotle was the first to organize the description of rhetoric, treating it as the counterpart of dialectic. He systematized deductive logic, and his ideas influenced Western thinking. Out of the five canons of rhetoric, he placed invention, or the discovery of lines of argument, at the very center of the rhetorical enterprise. Aristotle's genius with respect to rhetoric lay in his ability to incorporate all the situational elements occurring during the speaking situation: speaker, language, and audience during an oration. He was first to observe that speaking circumstances fall into three genres: forensic, deliberative, and epideictic (see section 'The Three Genres of Rhetoric', below). Aristotle's systematic account of rhetoric dominated rhetorical thought during the Middle Ages and beyond.

Roman rhetoricians, such as Cicero and Quintilian, drew largely on Greek rhetoric. The pseudo-Ciceronian *Ad Herennium* appears to be a representative Roman text in that it is essentially Greek in content and Roman in form. Much of the work by Roman writers is prescriptive, providing guidelines for using the basic rhetorical tools. Cicero distinguishes the five canons of rhetoric as a five-part structure of speeches: introduction, narration, statement of position, refutation, and conclusion (see section 'The Five Canons of Rhetoric' below). Although Cicero wrote two important handbook-style treatises, *De inventione* and *Topica*, he laid greater emphasis on his big dialogues on rhetoric, *De oratore* and *Orator*. Subsequent medieval traditions of rhetoric generally stressed the manuals. By contrast, Renaissance traditions favored the dialogues.

Living in the relative stability of the early Roman Empire, rather than during the political turbulence of the late Republic, as did Cicero, Quintilian did not have to justify the place of rhetoric. He developed the teaching of Cicero further and extrapolated it in a practical way. His aim was to train citizen-orators for the law courts and public life; the ideal was to be a good man skilled in speaking (*vir bonus dicendi peritus*). Quintilian's *Institutio oratoria* is considered the fullest rhetorical treatise in Latin; it sets forth a complete theory of invention, arrangement, style, memory, and delivery. This explains why it

became an important source of ideas on education throughout the Middle Ages.

Rhetoric underwent a decline with the fall of the Roman Empire and the decay of its heirs, the medieval institutions, to resurface only with the humanists during the Renaissance. It was subsequently challenged by such philosophers as Peter Ramus and John Locke and temporarily displaced by the rise of science and positivism. Rhetoric was, however, increasingly used in the democracies that emerged from the American and Western European bourgeois revolutions, which enabled it to be reborn once again and gradually secure an ever more outstanding position in modern society.

Defining Rhetoric

Today, more than 2000 years after the emergence of rhetoric and rhetorical thinking, scholars are still grappling with the intricate issues of its definition. Since rhetorical inquiry concerns human agents, symbol communication systems, and audiences, there are overlaps with related scholarly disciplines, such as linguistic pragmatics, argumentation theory, anthropology, psycholinguistics, and sociolinguistics, to name but a few.

It seems justifiable to agree with Scott (1972) that "any definition of rhetoric that is taken as once-and-for-all is apt to be gravely misleading," since any definition will only partly cover its wide range of uses. He suggests that any definition of 'rhetoric' will be, itself, a rhetorical use of language. At the same time, such a claim appears to contain its own contradiction: the claim that any definition of 'rhetoric' is a product of its rhetorical circumstances presupposes a basic definition of rhetoric.

The term 'rhetoric' is derived from the Greek *rhêtorikê* ('art/technique of a public speaker', from *eirein* 'to say, speak'), the earliest occurrences of which are among the followers of Socrates and more specifically in Plato's dialogue *Gorgias*. It is used there, somewhat pejoratively, to describe the technique of a public speaker or politician. The definition of 'rhetoric' as 'the art of persuasion' is the most common, although more nuanced definitions have often been provided. For Plato, rhetoric was "the art of winning the soul by discourse" (*Gorgias*). Aristotle made a point of distinguishing between rhetoric and persuasion. According to him, rhetoric "is the faculty of discovering in any given case the available means of persuasion" (*Rhetoric* 1.2.1). On a more programmatic note, Cicero regarded rhetoric as the eloquence able to persuade one's fellows of the truth of what they had discovered by reason (*De inventione*). These definitions point to a dualistic nature of rhetoric. On the one hand, 'rhetoric' is a skill used for a major purpose: to persuade. On the other hand, 'rhetoric' is the study and application of systematic reasoning, structuring, and communicating strategies.

Although rhetoric in Greece and Rome was primarily taught as an art of persuasive speaking or writing, it was widely recognized that rhetorical techniques were also employed in imaginative compositions not explicitly intended **to persuade** an audience to adopt some action or belief (although that might be present as a subtext), but aimed at an aesthetic effect, **to give enjoyment** to an audience or **to demonstrate the imaginative and linguistic skills** of the speaker or writer. Accordingly, the definition of rhetoric as the 'art of persuasion' might easily be extended to the 'art of effective expression'.

The Three Genres of Rhetoric

The main occasions for public address in classical Greece were in the law courts, in political assemblies, and on ceremonial occasions at public festivals. Aristotle (*Rhetoric* 1.3) outlined three different genres of rhetoric according to the role of the audience that is addressed: 'forensic' or 'judicial', 'deliberative' or 'political', and 'epideictic' or 'demonstrative'.

The target of 'forensic rhetoric' is an audience that is asked to make a decision about the justice or legality of an action in the past (e.g., trial speech). This genre was fully developed as a result of Greek constitutional democracy, whereby male citizens were required to speak on their own behalf in prosecution/defense in the courts of law. The goal was to persuade and ultimately to win.

The target of 'deliberative rhetoric' is an audience that is asked to make a decision about the advantages and disadvantages of a future action (e.g., a political decision). The function of deliberation in traditional societies is the achievement of consensus: not

Table 1 The three genres of rhetoric

Genres of rhetoric	*Temporal orientation*	*Means*	*Ends*	*Audience*
Deliberative	Future	Exhort and dissuade	Expedience, the dis/advantageous	Decision maker (legislator/voter)
Forensic	Past	Accuse and defend	The just and the unjust	Decision maker (judge/jury)
Epideictic	Present	Praise and blame	The noble and the shameful	Spectator

the acceptance of the view of a majority, but rather explicit or tacit unanimity, since it was felt that lack of unanimity was a threat not only to leaders but to the maintenance of a well-functioning democratic society.

The target of 'epideictic rhetoric' is an audience that is not required to make a decision, but to pass a judgment about an individual's character or deeds. This genre was regarded by Aristotle as a speech of praise or blame (funeral orations, anniversary speeches) that is concerned with what is honorable or dishonorable. Such speeches are connected with some ceremony meant to enhance traditional values.

As illustrated in Table 1, each of the three genres of rhetoric can be distinguished by its distinctive temporal orientation, means of persuasion, purpose, and the type of audience action called for.

The Five Canons of Rhetoric

According to Greek and Roman rhetoricians, five stages, called 'canons', needed to be followed in planning, structuring, and delivering a speech (the former terms are Greek and the latter Latin): *heuresis* or *inventio* 'invention'; *taxis* or *dispositio* 'arrangement'; *lexis* or *elocutio* 'style'; *mnēmē* or *memoria* 'memory'; and *hypokrisis* or *actio/pronuntiatio* 'delivery'. Each canon concerns a specific aspect of the process and production of discourse. While they may be laid out in a linear fashion, suggesting that discourse production is a linear process, rhetorical experience suggests that they are in fact recursive and interrelated activities.

'Invention' involves the search for adequate ways to present the information and to identify the arguments. It is tied to the rhetorical appeal of *logos*, being oriented to **what** an author would say rather than **how** this might be said.

'Arrangement' involves the organization and adjustment of the parts of a presentation in a coherent structure. In ancient rhetoric, arrangement referred solely to the order to be observed in an oration, but the term has broadened to also include large-scale discourse.

'Style' deals with rendering the contents in an appropriate and effective style. If invention addresses **what** is to be said, style addresses **how** this will be said. The concept of 'levels of style' comes essentially from the Roman rhetorical tradition, in which style was typically divided into three broad categories: high or grand, middle, and low.

'Memory' involves the deliberate use of mnemonic devices to remember the order of ideas and arguments in the speech. Typically, memory has to do only with the orator, but it invites consideration of how the audience will retain things in mind.

'Delivery' involves a good control of the vocal modulation and effective gestures that establish 'ethos' and 'pathos' appeals. It originally referred to oral rhetoric in a public context, but it concerns the presentation of both oral and written discourse.

The Three Rhetorical Appeals

With respect to invention, Aristotle and later rhetoricians made a distinction between 'artistic' and 'nonartistic' means of persuasion or rhetorical appeals. Nonartistic appeals are such things as the testimony of witnesses, written documents, and oaths that have been taken by litigants: they are 'used', but not 'invented'.

The artistic appeals in classical rhetoric are 'logos', 'ethos', and 'pathos'. Logos, or rational appeal of the message, is expected to provide the audience with good and sufficient reasons to believe and to act. Ethos, or ethical appeal (the character and authority of the communicator), should provide sufficient guarantee for the credibility of the message. Pathos, or the emotions conveyed in the message, should be powerful enough to engage audiences in terms of their own experience. As rhetoricians since Aristotle have convincingly shown (Bryant, 1973; Kennedy, 1999/1980; Corbett and Connors, 1999; Foss *et al.*, 1991), logos, ethos, and pathos are complementary in that they activate specific sides of the listener's mind and emotions to varying extents. The rhetorical appeals provide the audience with reasons and evidence for accepting or rejecting the beliefs, ideas, and feelings presented by the speaker.

Logos refers to the reasoning process of the speaker, whose claims are conveyed by means of two reasoning techniques, i.e., 'inductive' and 'deductive'. In Western rhetorical theory, inductive argument uses 'paradigms' that support a proposition by implying a universal conclusion from experience, which need not be expressed. Deductive argument involves the use of a rhetorical syllogism, called 'enthymeme'; it is usually probable, though not a certainty, and it tends to assume one premise that is unexpressed.

Another universal feature of logos is the use of *topoi* ('places' or 'topics'). There are two main categories of topics: 'common topics' and 'specific topics'. Common topics are strategies of argument applicable to many subjects and include definition, division of the question, and argument such as from the greater to the lesser, from cause to effect (or the opposite), and showing that something is possible or important (or the opposite). The other kind of topoi, 'specific topics', are appropriate to a particular subject.

Ethos was regarded by Aristotle as evidence that the speaker was to be trusted. For Aristotle, a speaker's ethos is persuasive when the speech demonstrates (1) *phronēsis* 'practical wisdom and common sense', (2) *arētē* 'moral virtue', and (3) *eunoia* 'goodwill toward the audience'. Later rhetoricians, such as Cicero, recognized, however, that there were other forms of ethos that regularly were involved in a speech. For example, a speaker might appeal to the moral character of the audience. In judicial rhetoric, the ethos of the opponent and of witnesses was often an issue. Ethos also has a nonartistic form – something that is brought to the occasion – such as the authority of the speaker, known to the audience from his/her position or previous actions.

Pathos was regarded by Aristotle as the emotion of the hearers aroused by a speech that moved them to accept what the speaker said. Cicero reconsidered the Aristotelian theory of ethos and pathos by reconceptualizing them as degrees of emotion: 'ethos' became thus an expression of moral character and of the gentler emotions associated with moral character, such as friendliness or pity; 'pathos' was regarded as the expression of strong emotions, such as anger or outrage. The nature and intensity of emotional appeals are generally influenced by culture and time. Rhetorical as well as pragmatic linguistic scholarship has shown that, for example, a statement that is amusing or conventional in one culture may be outrageous or insulting in another. Moreover, characteristics such as age, gender, and social status affect the pathos, or emotional impact, on different members of one and the same audience.

Classical Rhetoric in Postmodern Times

The 20th century, and especially the last 20 years, have seen a revival of rhetorical thinking in many disciplines also outside the university subject called 'rhetoric'. This is the result of a growing awareness that rhetoric permeates our thinking processes as well as our motivation to act. There is thus a rhetoric of science, a rhetoric of philosophy, a rhetoric of art, etc. The skill and theory of rhetoric involve a persuasion to feel and a persuasion to act. The relationships between reasoning, interpretation, and persuasion are being reconsidered and reevaluated in terms of meaning co-construction, emotional involvement, and ethical implications (Welch, 1990; Poulakos, 1993; Kastely, 1997; Gross and Walzer, 2000; Booth, 2004).

The study of rhetoric in postmodern times needs to examine critically how classical rhetorical issues have been theorized diachronically and synchronically and how the art and skill of rhetoric have been practiced in different times and places, by men and women (Lunsford, 1995; Glenn, 1997; Sutherland and Sutcliffe, 1999; Bizzell, 2000; Donawerth, 2002). The traditionally assumed distinctions between the roles of orators, audiences, and messages need to be challenged and examined critically to understand the rhetorical connections and disconnections between the communicative strategies associated with the ancient past and those emerging from the postmodern present.

Rhetoric: History

J J Murphy, University of California at Davis, Davis, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Rhetoric is the systematic analysis of human discourse for the purpose of identifying useful precepts for future discourse. Since it deals with human thought and expression, it has been linked through the centuries with psychology, philosophy, ethics (both private and public), and education.

Aristotle's Rhetoric

Rhetoric originated in ancient Greece, primarily in Athens, and was connected with a rising democracy that placed a premium on the speaking ability of each individual citizen. Even the philosopher Plato wrote on rhetoric, notably in his *Phaedrus*. The first major effort at a comprehensive theory of public speaking, however, was made by Aristotle in his *Rhetoric* (before 322 B.C.E.). He defined rhetoric as the faculty of observing in any given case the available means of persuasion. Aristotle named three types of orations: political, forensic, and epideictic (occasional). He declared that the object of rhetoric, persuasion, is achieved through the use of three 'proofs': *ethos*, the credibility of the speaker; *pathos*, the emotions of the audience; and *logos*, the arguments used. The main types of arguments are the example and the enthymeme, a rhetorical syllogism; Aristotle provided 28 sample 'topics' or lines of argument on which enthymemes can be based. He began Book Three by stating that it is not enough to know what to say; the speaker must also know how to say it. The subsequent discussion of style noted that the foundation of good style is correctness of language; at the same time Aristotle called for 'distinctiveness' of language, achieved through use of such devices as metaphors.

Interestingly, Aristotle's *Rhetoric* had very little influence in antiquity or the Middle Ages, becoming influential only after its translation into Latin in 1475 in Renaissance Italy.

Roman Rhetoric

Aristotle died in 322 B.C.E. We know very little about the development of rhetorical theory between that date and the emergence of a homogenous set of rhetorical doctrines shortly after 100 B.C.E. Though these ideas are embodied in his *De inventione* and six other rhetorical works of Marcus Tullius Cicero (105–43 B.C.E.), in the anonymous *Rhetorica ad Herennium* (c. 87 B.C.E.), and in the *Institutio oratoria* (95 C.E.) of Marcus Fabius Quintilian, the concepts are so similar in all these works that it seems fair to describe this common body of rhetorical doctrine as a 'Roman' rhetoric. It laid out five 'parts of rhetoric': (1) invention, the discovery of valid or seemingly valid arguments that render one's case plausible; (2) arrangement, the distribution of these arguments in a proper order; (3) style, the fitting of the proper language to the invented matter; (4) memory, the firm mental grasp of matter and words; and (5) delivery, the control of voice and body in a suitable manner. This theory of 'five parts' dominated Western rhetoric at least until the early 20th century and is still important today; its longevity is due at least in part to the fact that it is a natural progression of composition.

Roman invention included both 'topics' (as in Aristotle) and 'issues' or the points to be resolved in a controversy. In arrangement, the Romans specified a sequence of six parts of the oration itself: introduction, narration of background, partition (or outline of the case), confirmation, refutation, and peroration (conclusion). Style is identified under three levels – plain, middle, and grand – with distinction (*dignitas*) to be achieved through the use of 'fig-

Rhetoric is the systematic analysis of human discourse for the purpose of identifying useful precepts for future discourse. Since it deals with human thought and expression, it has been linked through the centuries with psychology, philosophy, ethics (both private and public), and education.

Aristotle's Rhetoric

Rhetoric originated in ancient Greece, primarily in Athens, and was connected with a rising democracy that placed a premium on the speaking ability of each individual citizen. Even the philosopher Plato wrote on rhetoric, notably in his *Phaedrus*. The first major effort at a comprehensive theory of public speaking, however, was made by Aristotle in his *Rhetoric* (before 322 B.C.E.). He defined rhetoric as the faculty of observing in any given case the available means of persuasion. Aristotle named three types of orations: political, forensic, and epideictic (occasional). He declared that the object of rhetoric, persuasion, is achieved through the use of three 'proofs': *ethos*, the credibility of the speaker; *pathos*, the emotions of the audience; and *logos*, the arguments used. The main types of arguments are the example and the enthymeme, a rhetorical syllogism; Aristotle provided 28 sample 'topics' or lines of argument on which enthymemes can be based. He began Book Three by stating that it is not enough to know what to say; the speaker must also know how to say it. The subsequent discussion of style noted that the foundation of good style is correctness of language; at the same time Aristotle called for 'distinctiveness' of language, achieved through use of such devices as metaphors.

Interestingly, Aristotle's *Rhetoric* had very little influence in antiquity or the Middle Ages, becoming influential only after its translation into Latin in 1475 in Renaissance Italy.

Roman Rhetoric

Aristotle died in 322 B.C.E. We know very little about the development of rhetorical theory between that date and the emergence of a homogenous set of rhetorical doctrines shortly after 100 B.C.E. Though these ideas are embodied in his *De inventione* and six other rhetorical works of Marcus Tullius Cicero (105–43 B.C.E.), in the anonymous *Rhetorica ad Herennium* (c. 87 B.C.E.), and in the *Institutio oratoria* (95 C.E.) of Marcus Fabius Quintilian, the concepts are so similar in all these works that it seems fair to describe this common body of rhetorical doctrine as a 'Roman' rhetoric. It laid out five 'parts of rhetoric': (1) invention, the discovery of valid or seemingly valid arguments that render one's case plausible; (2) arrangement, the distribution of these arguments in a proper order; (3) style, the fitting of the proper language to the invented matter; (4) memory, the firm mental grasp of matter and words; and (5) delivery, the control of voice and body in a suitable manner. This theory of 'five parts' dominated Western rhetoric at least until the early 20th century and is still important today; its longevity is due at least in part to the fact that it is a natural progression of composition.

Roman invention included both 'topics' (as in Aristotle) and 'issues' or the points to be resolved in a controversy. In arrangement, the Romans specified a sequence of six parts of the oration itself: introduction, narration of background, partition (or outline of the case), confirmation, refutation, and peroration (conclusion). Style is identified under three levels – plain, middle, and grand – with distinction (*dignitas*) to be achieved through the use of 'fig-

ures.' Book Four of the *Rhetorica ad Herennium* is the first to name 64 figures, divided into figures of speech and figures of thought, that were to become a standard for nearly two millennia; 10 of the figures of speech (e.g., metaphor, metonymy) later went under the name of 'Tropes.' So dominant was this set that this fourth book was often copied separately in the Middle Ages and Renaissance. The *Rhetorica ad Herennium* is also the first rhetorical treatise to offer a section on memory, involving the use of mental backgrounds into which mental images of remembered things can be placed. Delivery calls for the speaker's regulation of his voice, facial expression, and gestures.

The Roman educator Quintilian in his *Institutio oratoria* (95 C.E.) not only reinforced all these doctrines but outlined a systematic training program in grammar, literature, and rhetoric that set an educational standard followed for nearly 2000 years in Europe and America.

By the end of the classical period, then, a large number of sophisticated rhetorical concepts had been identified and combined into a well-coordinated, effective Roman system. In fact, some modern scholars, such as Brian Vickers and George A. Kennedy, evaluate later rhetorical developments according to the rate at which they accord with classical rhetoric.

Medieval Rhetoric

The Roman concept of 'seven liberal arts' – which included the subjects of grammar, rhetoric, and dialectic – was introduced into the Middle Ages by encyclopedists such as Martianus Capella, Isidore of Seville, and Cassiodorus. These encyclopedists offered highly condensed abstracts of rhetorical lore, usually without examples. They were, however, a main source of knowledge about rhetoric for many in the Middle Ages. The copying of Ciceronian rhetorical texts, especially his *De inventione* and the anonymous *Rhetorica ad Herennium* generally ascribed to him, continued throughout the Middle Ages; these were often accompanied by glosses or commentaries – usually a sign that the texts were used for teaching in schools. It is important to note that during the Middle Ages, rhetoric was taught in what we would call secondary schools, rather than in universities.

Aristotle's *Rhetoric* was copied often in Latin translation, but not used as a rhetoric text; instead it was typically included in manuscript collections on moral philosophy.

The original rhetorical treatises composed during the Middle Ages fall into three categories, each a separate rhetorical genre. The first, developed in the 11th century, was the *ars dictaminis*, or art of letter-writing. Basically this art took the Ciceronian pattern of six parts of an oration and set up a five-part format for writing a letter: salutation (based on the social level of writer and addressee), introduction, narration, petition, and conclusion. Many of the 300 surviving dictaminal manuscripts are accompanied by model letters. All are in Latin. The second genre, the *ars poetriae* or art of writing poetry, was in teaching practice, the art of writing both verse and prose. The *Poetria nova* (c. 1210) of Geoffrey of Vinsauf was the most important of the six major Latin works that appeared between 1170 and 1280. Relying heavily on the *Rhetorica ad Herennium*, including the use of all 64 figures from the fourth book of that text, Vinsauf laid out a Ciceronian pattern for the composition of verse and prose. The fact that it survives in 200 manuscripts indicates that the book was enormously popular. It is important to note that in the Middle Ages poetry (and some prose) was meant to be read aloud, so the application of Ciceronian rhetorical principles to poetry was not as unusual as it might seem to modern readers. All the authors of the *ars poetriae* were grammarians, and in fact one of them, John of Garland in his *De arte prosayca, metrica at rithmica* (after 1229), tried to establish a linguistic base for all language use.

The third medieval rhetorical genre was the *ars praedicandi*, or art of preaching.

The medieval oral sermon shared some of the characteristics of the ancient oration, but the circumstances were quite different. Persuasion was not the objective, since the congregation consisted of people already committed to Christianity. Consequently, the emphasis was on explanation and reminders of the text of the Bible. More than 300 separate 'arts of preaching' appeared between approximately 1200 and 1500, following a basic format of elaborating on a 'theme' (usually a passage from Scripture). The theme was divided into parts (usually three), each part was then redivided, and each of these parts was 'amplified' or 'proved' in a variety of ways. Some commonly used means of amplification were the exemplum (narrative example), authority, reasoning, etymology, allegory, and metaphor. Despite the oral nature of the sermon, the treatises seldom discuss delivery.

The Renaissance

Two factors led to an explosion of interest in rhetoric in early modern Europe. One was the recovery of all the ancient rhetorical works of Greece and Rome, most of which had not been known during the Middle Ages. For example, the complete text of Quintilian's *Institutes of oratory* was discovered in Switzerland in

1417, and Greek texts were brought to Italy from places such as Constantinople for study by humanist scholars.

The other factor was the advent of printing. A staggering number of rhetoric texts were printed between 1465 and 1700: Lawrence D. Green and James J. Murphy have identified 3842 titles by 1717 named authors and 120 anonymous authors, produced in 310 printing towns by 3340 printers and publishers.

It is obviously impossible to summarize all the developments during this period, but some important features are the application of classical rhetoric to preaching, the attack of the new empirical science on the epistemological assumptions of classical rhetoric, the rise of 'general rhetoric' (an amalgam of Greek and Roman sources), and the gradual democratizing of rhetoric from an elite Latin to a popular vernacular art. One particular development, though, is important enough to note. The French university master Peter Ramus, following the lead of Rudolph Agricola's work on logic, declared in 1543 that Aristotle, Cicero, and Quintilian were all wrong about rhetoric. He assigned Invention and Arrangement to dialectic, leaving only Style and Delivery to rhetoric (and leaving Memory out as a separate part). Ramus was immensely popular, especially in Protestant countries, and had great influence in colonial America as well. Walter J. Ong has calculated that 1400 editions of his and his followers' works were printed. The resulting controversy between Ramists and Ciceronians lasted well into the next century.

Modern Rhetoric

Since 1700, rhetoric has gone from being an integral part of education and civic life to an ignored or even opposed entity today. Some even believe that rhetoric today is so diluted in its efforts to be all-encompassing that it is difficult to identify the core of the subject. But there has been no single climactic event to which this change can be assigned. Of course, there have been many variations of basic rhetorical theories and there have been differences in emphasis on one part of rhetoric or another. For example, the so-called 'elocutionary movement' of the 18th century in works by authors such as Thomas Sheridan and Gilbert Austin focused on pronunciation and other aspects of delivery. The Scotsman George Campbell argued in his *Philosophy of rhetoric* that to achieve persuasion rhetoric must address four 'faculties' of the mind – the understanding, the imagination, the passions, and the will; he also declares scientific linguistics to be the foundation of rhetoric. The 'belletristic movement' linked rhetoric, literature, and 'taste,' as marked in books such as the influential *Lectures on rhetoric and belles lettres* (1793) of the Scotsman Hugh Blair. Another Scottish development, linked to growing demands for socially advancing education, was the application of rhetoric to writing – a movement that was to affect pedagogy in the United States. The 19th century philosopher Friedrich Nietzsche declared that language is rhetoric, because it can express only opinion, not knowledge; consequently 'truth' can be seen as a linguistic social agreement rather than objective fact. In the opinion of rhetorical historians Patricia Bizzell and Bruce Herzberg, Nietzsche anticipates themes developed by 20th-century rhetoricians such as I. A. Richards, Richard Weaver, and Chaim Perelman, as well as philosophers Michael Foucault and Jacques Derrida. Finally, the application of the methods of social science to discourse analysis in recent years has produced a field of 'communication' markedly different from a rhetoric relying on thought and on perceptions by individuals.

At the beginning of the 21st century, then, rhetoric is like the multistream delta of a long river that spreads its central channel into a variety of channels. This is perhaps, not surprising, after such a long history.

Rhetoric: Semiotic Approaches

Introduction

'Rhetorics' is a polysemic word. All the meanings connected with it fall into two major groups: in the first one, rhetorics is regarded in a narrower and more traditional sense, in relation to verbal texts; in the second one, rhetorics is treated in a more universal and modern sense, in relation to expressing any information (e.g., visual rhetorics). It is nevertheless clear in both cases that rhetorics operates with signs and therefore fits completely into the framework of semiotics. Consequently, we could regard rhetorics simply as part of semiotics and semiotics as the ground for rhetorics. On the other hand, Charles Sanders Peirce distinguished three aspects of semiotics (Peirce identified semiotics with logic): speculative grammar, speculative critic, and speculative rhetoric (Peirce, 2.93). Thus, it is rhetorics rather than semiotics that proves to be a more general and basic knowledge. Attention needs to been drawn to the dangers of terminological amorphousness resulting from the nondistinction of rhetorics and metarhetorics; in order to avoid this, we will further speak of rhetoric phenomena when we refer to the object level, and of rhetorical phenomena when we refer to the metalevel.

Different treatments of rhetorics within the semiotic framework complicate the matter even more, since there is no clarity even in the approaches, not to mention the basic concepts. The researchers proceeding from the Peircean tradition drew attention to the fact that the most important tropes – metaphor and metonymy – are clearly related to the **icon**ical and **index**ical signs (Jakobson, 1956, 1980; Shapiro and Shapiro, 1976). Saussure's disciples, on the other hand, used the concepts and methods of structural linguistics and text grammatics to describe rhetoric phenomena, which gave rise to different directions of structural rhetorics (e.g., Dubois *et al*., 1970), as well as to deconstructional rhetorics, which was in clear opposition with both traditional and structural rhetorics (e.g., de Man, 1986). An entirely different approach to certain rhetoric phenomena (above all, metaphor and irony) developed within the framework of analytical philosophy (cf. Searle, 1979); from the cognitive linguistics evolved the "everyday rhetorics" (Lakoff and Johnson, 1980). To this, Paul Ricoeur's hermeneutical approach to metaphor (Ricoeur, 1975) and a whole range of *ad hoc* linguistic, philosophical, and poetical treatments of different tropes and figures should be added. Some approaches focus on the rhetoric structure of the text; others focus on characterizing different styles, movements, or genres; yet others, on describing different figures and tropes (primarily metaphor) or on solving problems related to the transfer of meaning, etc. At first sight, all this presents an ambiguous picture of the landscape of contemporary rhetorics.

Before we discuss the semiotic aspects of rhetorics, it is necessary to determine what rhetorics is as a whole – or, to be more specific, what is the field where the phenomenon of rhetorics emerges – and second, how and to what extent the semiotical analysis could approach it.

Rhetoric: Semiotic Approaches

Introduction

'Rhetorics' is a polysemic word. All the meanings connected with it fall into two major groups: in the first one, rhetorics is regarded in a narrower and more traditional sense, in relation to verbal texts; in the second one, rhetorics is treated in a more universal and modern sense, in relation to expressing any information (e.g., visual rhetorics). It is nevertheless clear in both cases that rhetorics operates with signs and therefore fits completely into the framework of semiotics. Consequently, we could regard rhetorics simply as part of semiotics and semiotics as the ground for rhetorics. On the other hand, Charles Sanders Peirce distinguished three aspects of semiotics (Peirce identified semiotics with logic): speculative grammar, speculative critic, and speculative rhetoric (Peirce, 2.93). Thus, it is rhetorics rather than semiotics that proves to be a more general and basic knowledge. Attention needs to been drawn to the dangers of terminological amorphousness resulting from the nondistinction of rhetorics and metarhetorics; in order to avoid this, we will further speak of rhetoric phenomena when we refer to the object level, and of rhetorical phenomena when we refer to the metalevel.

Different treatments of rhetorics within the semiotic framework complicate the matter even more, since there is no clarity even in the approaches, not to mention the basic concepts. The researchers proceeding from the Peircean tradition drew attention to the fact that the most important tropes – metaphor and metonymy – are clearly related to the **icon**ical and **index**ical signs (Jakobson, 1956, 1980; Shapiro and Shapiro, 1976). Saussure's disciples, on the other hand, used the concepts and methods of structural linguistics and text grammatics to describe rhetoric phenomena, which gave rise to different directions of structural rhetorics (e.g., Dubois *et al*., 1970), as well as to deconstructional rhetorics, which was in clear opposition with both traditional and structural rhetorics (e.g., de Man, 1986). An entirely different approach to certain rhetoric phenomena (above all, metaphor and irony) developed within the framework of analytical philosophy (cf. Searle, 1979); from the cognitive linguistics evolved the "everyday rhetorics" (Lakoff and Johnson, 1980). To this, Paul Ricoeur's hermeneutical approach to metaphor (Ricoeur, 1975) and a whole range of *ad hoc* linguistic, philosophical, and poetical treatments of different tropes and figures should be added. Some approaches focus on the rhetoric structure of the text; others focus on characterizing different styles, movements, or genres; yet others, on describing different figures and tropes (primarily metaphor) or on solving problems related to the transfer of meaning, etc. At first sight, all this presents an ambiguous picture of the landscape of contemporary rhetorics.

Before we discuss the semiotic aspects of rhetorics, it is necessary to determine what rhetorics is as a whole – or, to be more specific, what is the field where the phenomenon of rhetorics emerges – and second, how and to what extent the semiotical analysis could approach it.

Ancient Rhetorics

Human nature is universal: in different cultures independently of one another evolves congeneric knowledge related to astronomy, geometry, physics, medicine, etc. The existence of linguistic and poetic doctrines is also rather universal. Against this background, rhetorics has an unusual history: it originated in the specific settings of the Ancient Greek civilization, and all the subsequent rhetorical schools and traditions have derived from this source. No other ancient culture has developed anything that could be likened to classical rhetorics. This fact is even more remarkable as rhetorical matter is unspecific: all rhetoric phenomena can be entirely distributed among grammar, stylistics, poetics, and logic. Thus, most *rhetoric figures* and *tropes* have analogues in Persian, Arabic, Indian, as well as Chinese poetical traditions. Moreover, for instance Aristotle, within the Greek tradition itself, discusses the same phenomena in his *Rhetorics* and *Poetics*. The differences between these lie not in the matter but in the purpose: the aim of the poetic text is catharsis; that of the rhetoric text, to convince a listener.

The specific setting that made possible the rise of rhetorics in the European civilization involved the liberation from tyranny and the establishment of democracy in Athens and the restoration of usurped land to its legal owners. In a culture with no written ownership acts, the oral public word became the main tool in the settlement of disputes, and, above all, legal disputes. Rhetorics as an art of speech grew out of the practical needs of democratic institutions (republic, public political competition, freedom of speech, public justice); court and political speeches became the most important rhetoric genres.

Of course, Greek culture was not the only one where the art of public speech was fostered: Japanese, Chinese, and Muslim cultures present remarkable examples of this kind. Nevertheless, the corresponding fields cannot be really compared to ancient rhetorics, as in their case we are rather dealing with poetics, speech etiquette, etc. Rhetorics needs freedom and competitive public debate in the condition of equality of debate partners; speakers enter the contest where their only resources and weaponry are words and the skill of using them.

Even those schools of rhetoric that were primarily oriented toward ornamental style (the Asian school) – or those that claimed, similarly to Gorgias and in the spirit of Sophists, that they could prove anything – pursued the right influence of speech, i.e., they proceeded not from the semantic but from the pragmatic notion of truth. Thus, Gorgias compares his speeches to *pharmakon* ('drug') that a speaker uses to take his listener to a desired state of mind. In any case, ancient speech practice usually regarded ornaments as tools, not as an aim *per se*. It is informative to compare Greek rhetorics with Sanskrit poetics, since both evolved from the same Indo-European tradition. In the older stratum of the Sanskrit poetics (which has been preserved in Bhamaha's and Dandi's treatises of the 7th and 8th centuries) the central concept is *alankara* ('ornament'), which is comparable to the Greek *schema* ('figure'). The aesthetics of *alankaras* is very simple: the more ornaments there are and the more complex the constructions they form, the higher is the aesthetical value of an utterance. The later Indian tradition focused on the concept of *dhvani* (Anandavardhana's *Dhvanyaloka,* 9th century), which is not easy to translate: it is a hidden image, not expressed through words. Although the mechanistic doctrine of *alankaras* differs radically from the spiritualistic teaching of *dhvani*, both are entirely different from the Greek concept of rhetorics, where *schemata* do not have a sovereign value and every meaning can be expressed through word.

As it became an independent discipline, rhetorics had to define and position itself in relation to other branches of learning. Rhetorics opposed poetics as a skill of verbalizing real events against the skill of verbalizing fictional events; rhetorics opposed dialectics as an art of monological speech against the art of dialogue; rhetorics opposed logic as an art of expressing one's thoughts against the art of thinking (according to Aristotle, rhetorics is something like applied logic; logic which uses syllogisms is an art of proving, rhetoric is an art of persuasion, instead of syllogism it uses *soriteses* consisting of *enthymemata*), etc. Already by the 5th century B.C., there had emerged an intuitive notion of truth that could be termed the *rhetorical ideal*. According to this ideal, thinking, speaking, and acting form an inseparable complex: it is possible for a human being to develop and formulate his or her thoughts and ideas properly (the sphere of logic), to express them properly (rhetorics), and, in accordance with these, to act properly (justice). In the Roman Republic, rhetorics became even more connected with truth and justice; i.e., Cicero treated such 'hermeneutical' problems like the use of torture during the interrogation. Rhetorical ideal, which provided a foundation for the European mentality, prevailed at least until the 18th century and applies to some extent today. The rhetorical ideal was based on the intuition that the road to truth is the straightest of all possible roads and has to be followed in one's thoughts, words, and actions. An outstanding 17th-century pedagogue, Jan Amos Komensky, started his treatise *Orbis sensualium pictus* (1658), which was

intended to be a textbook, with a definition of wisdom: "*recte intellegere, recte agere, recte eloqui*" ("to comprehend properly, to act properly, to speak properly"). It is important to emphasize that an initial conception of rhetorics treated it as the art of speaking the truth.

Classical rhetorics consisted of five subdivisions: (1) invention (*heuresis*, *inventio*), (2) arrangement (*taxis, dispositio*), (3) style (*lexis*, *elocutio*), (4) memory (*mneme, memoria*), (5) delivery (*hypokrisis*, *pronuntiatio*). These subdivisions formed a logical whole, but at the same time their sequence marked an ideal succession of rhetoric activities that corresponded to the rhetorical ideal: the logical sequence expresses itself on the operational level.

During the Roman Empire, public speech lost its social role related to the seeking and expressing of truth. This diminished greatly the relevance of the first and, to a large extent, the second subdivision. The spread of the written word reduced the importance of also the fifth and especially the fourth subdivision. In contrast, the significance of the third subdivision had been increasing since the Hellenistic period. In the Middle Ages, the field of rhetorics was divided in two: the first, speculative rhetorics, became essentially a part of scholastic philosophy, which focused on the classifications of figures and tropes. As a practical oratory, rhetorics retained its relevance in sermons, forming the sphere of homiletics.

At the same time, already in the late antiquity but especially in the Middle Ages, rhetorics started to interfere with poetics, above all with regard to written texts. Rhetorics became the teaching of prose. It is interesting that even Dante and Petrarca in their Italian prose attempted to follow instructions for *cadentia* at the ends of periods. Consequently, at least for the early humanists, the Latin speech rhythm codified by Cicero became the general principle of style for written language. The decline of scholastic philosophy and the secularization of culture inevitably led to the crisis of rhetorics.

The first criticism of rhetorics evolved in the context of rationalism and especially of the philosophy of enlightenment. The crisis of rhetorics was inseparably connected with the crisis of (Aristotelian) logic. For instance, in Molière's play *The would-be gentleman* (1670), the teacher of logic and rhetorics is presented as a charlatan. For Molière, Rousseau, and others, rhetorics came to mean the art of lying; truth required no skills. Interestingly enough, the crisis of rhetorics stemmed also from the rhetorical ideal (the purpose of speech is to approach the truth); only the notion of rhetorics changed: it was now regarded as an art of evasion.

The rhetorical ideal survived the classical rhetorics; we can come across its reflexes in the modern Western civilization in such different spheres as analytical philosophy, which advanced the notion that telling the truth is a simpler and more logical way of speaking than lying, and the assessment of utterances with the help of a lie detector, a practice based on the presumption that the organism of a lying person undergoes psychosomatic changes.

Ancient Semiotics and Rhetorics

Although the first treatise devoted to semiotics – *Cratylus* by Plato – had by the 5th century B.C. already been written, semiotics as a discipline and even the word 'semiotics' was then unfamiliar. In antiquity, rhetorics as a branch of knowledge was not related to the semiotics of that time. *Cratylus* focused on the problem of the motivation of sign without relating this to the art of speech. In *Phaedrus* we encounter both semiotical and rhetorical issues, but these were not brought together.

Probably the first to use the term 'semiotics' was a doctor and medical theoretician, the developer of the Hippocratic tradition Galen (2nd century A.D.); he employed it to refer to symptomatology – in modern terms, diagnostics. It should be emphasized that such treatment of semiotics has no connection with rhetorics. Ancient (medical) semiotics belongs to the sphere of what Carlo Ginzburg calls "the evidential paradigm."

It could be said that this paradigm is in direct opposition to the spirit of rhetorics: the basis of rhetorics is the skill of speaking the truth and a notion that truth is simple and logical, while telling the truth can be governed by *a priori* fixed rules; semiotics, on the other hand, studies indirect signs to find out the unsaid truth and takes roundabout routes – one and the same disease can have different symptoms.

To modern semiotics, however, rhetorics is the closest of all the ancient spheres of knowledge. Many problems of contemporary semiotics (denotation, the relationship between name and description, etc.) found their first treatment precisely in ancient rhetorics. In addition, there are clear correlations between the principal dimensions of semiotics and the main subdivisions of classical rhetorics: the syntactical approach reveals itself in arrangement and partially also in style; the semantical approach can be observed both in invention and in style – in the case of invention, we are dealing with strong, referential semantics; in the case of style, with weak, significative semantics; the pragmatic approach manifests itself in memory and pronunciation.

Structural Rhetorics

The crisis of rhetorics lasted until the middle of the 20th century, when structural linguistics rediscovered tropes and figures. A central figure of structural rhetorics was Roman Jakobson, who linked different tropes with art forms and schools on the one hand and with different cognitive processes on the other hand. These phenomena had never before been related to rhetorics, which therefore meant a substantial expansion of the field of rhetorics; at the same time, Jakobson reduced the whole subject matter of rhetorics to two tropes, metaphor and metonymy, and treated these as universal semiotic mechanisms. Metaphor is the basis for the mechanisms of romanticism and poetry; metonymy, for that of realism and prose. According to Jakobson, the grounds for metaphor and metonymy could be found in the structure of natural language, in its two axes. The axis of combination (syntagmatics, in Jakobson's words) was the basis of metonymical relations; the axis of selection (paradigmatics), that of metaphorical relations. Since according to Jakobson the mechanism of poetry lay in the projection from the axis of selection onto the axis of combination – which led to the organization of sequences in verse according to the principle of equivalence – it is clear why verse is dominated by metaphor. However, in the case of prose, we are dealing with pure sequence, which creates a basis for the predominance of metonymy.

All this, in turn, correlates on the one hand with the difference between visual and acoustic signs and on the other with the functional asymmetry of the brain. Comparing fine arts and music, Jakobson called attention to the fact that the first is governed mostly by the principle of iconicity – i.e., the signifier is motivated by the signified, and so-called abstract art based on arbitrary signs is always problematic. At the same time, in music the situation is reversed: music employs predominantly arbitrary signs or symbols, and so-called concrete music based on icons (e.g., the sound of a cuckoo) and indexes (e.g., the whistle of a train as a sign of journey) – even if it does not cause displeasure – is clearly a different kind of music. Jakobson concludes that visual and acoustic information differ in principle: for some reason our eyes prefer to trust icons, but our ears tend to trust symbols. Visual signs represent space, and the principles of space are symmetry and similarity – i.e., equivalence. Acoustic signs represent time; their principle is sequence. Again, all this is related to the functional asymmetry of the brain. The subdominant (usually right) hemisphere is oriented toward visual information and its metaphorical treatment; although the prevailing sign type is icon, indexes belong to this sphere as well. The dominant (usually left) hemisphere is oriented toward acoustical information, metonymy; the prevailing sign type is symbol.

Yuri Lotman drew on Jakobson's approach but made some important additions and elaborations. First of all, Lotman argued that the sphere of rhetorics cannot come into being on the basis of only one (e.g., natural) language: rhetoric phenomena emerge when at least two semiotically different languages collide. Already the basic concepts of rhetorics – 'image,' 'figure,' etc. – have clear connotations of the visual sphere. Lotman drew attention to the fact that a large number of metaphors are related to the visual semantics, but visuality alone is not sufficient: visual information has to be transmitted by verbal means. Thus, metaphor is a translation from the language operating with visual signs into the verbal language. These languages have different semiotic statuses: visual codes are mimetic, are founded on iconicity, and are continual, while verbal codes are discursive, are discrete, and are founded on symbolism. Even when a metaphor or a metaphorical epithet is not related to a visual image (e.g., 'sweet dreams'), we are still dealing with the recoding of iconic information by means of symbols. The above is characteristic of the traditional sphere of rhetorics, but Lotman recognized the possibility of a reverse situation as well: information encoded with a symbolic code can be transmitted through an iconic code. This way visual symbols are formed, and here too we can speak of different tropes – e.g., visual metaphor and metonymy. While verbal images come into being through the transmitting of visual messages by verbal means, visual images emerge through the transmitting of verbal messages by visual means.

Structural Rhetorics and Text Theory

Independently of Jakobson, but simultaneously with his work of solving rhetorical problems with the help of modern linguistic and semiotic methods, the peripheral areas of linguistics developed a contact with topics that traditionally belonged to the sphere of rhetorics. As late as the middle of the 20th century, linguistics still considered the sentence to be the maximum unit of language (Émile Benveniste even presented special arguments in favor of this view). But by 1952, Zellig S. Harris demonstrated that syntactic relations between constituents cross the sentence boundaries. From this observation evolved text linguistics, one of the leading areas of linguistics during the years 1970–1980. Within the field of text linguistics, different tendencies can be discerned. There were authors who, in the spirit of Harris,

confined themselves to purely formal textual parameters, such as (a) anaphoric repetitions (in contrast to classical rhetorics, which held that anaphora could occur only at the beginning of a colon or a period, text linguistics understood anaphora in a much wider sense: as any lexical repetitions in different syntactic sections); (b) substitution of lexemes with pronouns in consecutive sentences; (c) grammatical restraints that exceed sentence boundaries (Gasparov, 1971). Other authors examined syntactic relations between sentences in a wider semantic and pragmatic context (Van Dijk, 1972, 1981). Pragmatic aspects come in, in connection with describing the communicative structure of the relations between sentences.

It has been observed that sentences join into a coherent text according to a certain rule: what is the rheme in a previous sentence becomes the theme in the next. In contrast to Harris, who operated mainly with the terms of sentence structure, in such an approach the main element becomes text as a communicative whole. Although text theorists seldom refer to classical rhetorics, they deal with similar problems. The structure of a coherent text is based on repetitions on different levels, and the majority of rhetoric figures and tropes (anaphora, epistrophe, symploce, alliteration, parallelism, antithesis, simile, etc.) follow the same principle. When we look at a text as a whole, we can see that the use of tropes forms a definite system in the text. For example, if a text contains many metaphors, it is likely to also have plenty of similes and epithets. If metonymies prevail, synecdoche and irony tend to appear frequently as well.

The Semantic Foundations of Structural Rhetorics

Already Roman Jakobson in his study of tropes paid close attention, in the spirit of the Prague Linguistic Circle, to semantic elements smaller than words. This made it possible for us to be considerably more specific than the ancient teaching of tropes as figures of thought. For example, when we speak of transferred meaning in the case of metaphors, it is clear that what is transferred is not the whole meaning of the word but only a part of it. Different models of structural rhetorics approached the problem of the figurative meaning differently. For instance, if we proceed from the concept of semantic fields, we can represent meaning as space in the topological sense. In such a case, metaphor can be described as an intersection of two semantic fields, and the more distant the meanings are, the stronger the effect of the metaphor is. Greater influence, however, was gained by an approach based on the componential analysis of meaning. If we picture the meaning of a word as a matrix of markers and distinctors (to use the terms of Jerrold J. Katz and Jerry A. Fodor), the metaphorical expressions can be described as constructions where the *vehicle* projects one or several of his markers onto the *tenor*.

An important role in the description of language-semantic mechanisms of metaphor has been played by Uriel Weinreich (1966). He demonstrated that semantic syntax is not based on only one operation (as Katz and Fodor assumed), an operation that could be called "linking of meanings," but that there exists at least one more relationship – 'nesting,' in Weinreich's vocabulary. Thus, if we represent the meaning of a word in the form of a matrix, we have to accept the possibility that the matrix contains another matrix as its component. In addition, he argued that rules of semantic syntax could be formulated more effectively if we assumed that the matrices of meaning might contain lacunae in which the components of meaning could be nested. Different operations produce different tropes. Linking creates epithets: for instance, linking the meaning 'ball' with the component 'red' produces the expression 'red ball.' However, it must be added that this mechanism characterizes only modern epithets oriented toward creating new information; archaic epithets, on the contrary, are pleonastic, utterly redundant. For instance, in the expression 'round ball,' roundness is not linked to the meaning 'ball' but instead extracted from it. Metaphor, on the other hand, is created as a result of nesting. Unlike Katz and Fodor, Weinreich does not regard expressions like "a rock is dreaming" as having a conflict in semantic syntax: 'rock' [– *alive*] cannot be joined to 'dreaming' [+ *alive*]; 'dreaming' is nested in 'rock.' A classification of different rhetoric tropes and figures deriving from componential analysis was proposed by Groupe μ (Dubois *et al.*, 1970).

Pragmatic Rhetorics

The various branches of structural rhetorics differed substantially in their purposes from the classical rhetorics. All of the new branches are occupied with the structure of text, not its effect, and therefore the approaches of both Roman Jakobson and Groupe μ pertained more to the field of poetics than to that of rhetorics. Speech act theory, together with the adjacent fields, can be regarded as an attempt to revive, with the tools of modern philosophy, the rhetorical ideal, according to which *plan*, *construction*, and *activity* form an inseparable unity and at the same time a natural sequence. John L. Austin, regarding language activity, joins the first two (plan and con-

struction) under the name "locutionary speech act," names the third one (action) "illocutionary act," and adds to these *consequence*, under the name "perlocutionary act." (Classical rhetorics was not concerned with the effect of speeches, but it is clear that the principle of perlocutionarity derives from the spirit of rhetorics, which regards speech as a responsible activity.) For example, John Searle's discussion of metaphor from the perspective of speech act theory represented the return of the aims of classical rhetorics. At the same time, in comparison with that of classical rhetorics, Searle's approach was clearly much more limited – of all the tropes and figures, he paid attention only to metaphor and irony (it has often been questioned whether the latter should be regarded as a trope at all).

Searle's approach was above all characterized by his position that metaphor is not a figure of thought obtained by the joining of words but rather an utterance. Furthermore, Searle argued that such a phenomenon as figurative meaning does not and cannot exist at all: words and sentences mean what they mean. The phenomenon of metaphoricality emerges not in words but in their use and, hence, not in the field of semantics but in pragmatics. Searle proposed the following hierarchy: direct speech acts, indirect speech acts, metaphor, irony. Metaphor emerges when the sentence meaning diverges from the utterance meaning. Searle distinguished between simple and complex metaphors: in the first case, the relationship between a sentence and an utterance is one-to-one; in the second case, several utterances correspond to one sentence. However, in both cases the utterance meaning can be inferred from the sentence meaning.

The rhetorics based on the speech act theory is the complete opposite of George Lakoff and Mark Johnson's "everyday rhetorics": whereas Searle accepted only the literary meaning, for Lakoff and Johnson the figurative word use was basic. Lakoff and Johnson's approach resolutely dismissed the traditional teaching of metaphor, which rested on an assumption that there exists a neutral, nonfigurative speech that an author embellishes with figures and tropes. They pointed out that there is no such thing as a neutral, nonmetaphoric background in language: common speech is full of metaphors, but speakers and listeners usually do not notice them, since they live by them. Lakoff and Johnson demonstrated that metaphors are not accidental semantic curiosities; rather, they have a systemic nature that has a great influence on the speakers' worldview. One of Lakoff and Johnson's examples concerned speech activity. The metaphorical expression "argument is war" forms an entire linguo-cultural paradigm that treats different aspects of argument in terms of warfare. Although it seems that the relationship between the approaches of Searle and of Lakoff-Johnson is antagonistic, they complement each other substantially. Speaking cannot be totally controlled by reason and entirely imposed by discourse and culture. The processes described by Searle and Lakoff-Johnson form two opposite poles in the continuum of speech activity. Russian philosopher Mikhail Bakhtin raised an analogical problem in his work *Toward a philosophy of the act* (1919–1924), Bakhtin's doctrine was named the rhetoric of act. Act is not any deed, but only a meaningful and responsible one – i.e., it changes *status quo*, and an agent takes a full responsibility for it. The speech act theory is very close to Bakhtin's views.

Rhetorics and Semiotics of Culture

From the viewpoint of the semiotics of culture, two levels of rhetorics should be distinguished: implicit rhetorics as a strategy of generating texts (on this level, rhetorics is a cultural universal), and explicit rhetorics (or rhetorics in the direct sense of the word) as a teaching of generating texts. The semiotics of culture, especially the semiotics of culture of the Tartu-Moscow school, is characterized by an an extended understanding of text: text is a vehicle not only of verbal but of any kind of information; text is a signal that an addresser sends to an adressee, and in the positions of both the sender and receiver, there can appear individuals and social groups as well as whole cultures. In this sense it is possible to regard, for example, ballets, commercials, chess games, election campaigns, and wars as texts. Every such text has its own grammar, stylistics, and rhetorics. From the viewpoint of cultural typology, each culture displays its own clear rhetorical characteristics. The Western European rhetorical ideal is simplicity and straightforwardness, based on Cratylean understanding that things have their right names and speech activity is controlled by reason. It is interesting that although the expression "the beginning of wisdom is to call things by their right names" is attributed to Confucius, in Chinese and in Far Eastern speech practice in general, there prevail indirect speech strategies and an idea that many different roads lead to truth. Such understanding permeates different strata of culture: for instance, we can see how the rules of rhetorics are reflected in the art of warfare. The metaphor "argument is war," analyzed by Lakoff and Johnson, is effective in different cultures; at the same time, it reflects the important characteristics of these cultures. While European warfare, which developed from the ancient model, focuses on two main opera-

tions – attack and defense – in the Chinese art of warfare, the central role is played by the roundabout maneuver; the highest art of warfare lies not in the battle but in avoiding the battle: "The skillful leader subdues the enemy's troops without any fighting; he captures their cities without laying siege to them; he overthrows their kingdom without lengthy operations in the field" (Sun Tzu, *The Art of War*). The differences between the Greek and the Chinese arts of war reflect the leading strategies in the speech etiquettes of these cultures. Whereas the Greek orator and military leader both build their argumentation resp. military forces following ideal forms (e.g., in Plato's case, the ideal for both rhetorics and warfare is geometry) with the aim of destroying the opponent's argumentation resp. military forces, the Chinese art of war follows the prevailing rule of Chinese speech etiquette, according to which the speaker (especially when the speech is directed to an equal or a superior) cannot express the message explicitly: a speech act is considered successful if the adressee receives the information without the speaker's having expressed it directly – the problem is solved without a debate (Jullien, 1995).

It would be an extreme oversimplification to link two rhetoric strategies rigidly with geographical parameters of different cultures: we come across both mechanisms in the East as well as in the West; what becomes decisive is their proportion. Even in the context of Western European culture, H. Paul Grice's maxims of conversation and Searle's treatment of speech acts should be characterized as a utopian ideal picture that is never achieved in a real communication. Yuri Lotman pointed out that in Europe, different periods are dominated by different rhetoric strategies, but unlike Jakobson, he refrained from straightforwardly associating them with Romanticism and realism. For example, mannerist literature and the speech practices of marginal groups in the era of Romanticism (the parlance of English dandies, the language of French precious ladies, etc.) are clearly oriented toward indirect speech acts, the use of descriptions instead of naming: these are exactly the aspects that attract the attention of a European in the Far Eastern speech etiquette.

Rhetorical Structure Theory

Introduction: What is Rhetorical Structure Theory?

Readers feel that natural texts are coherent and well structured, and that texts achieve rhetorical goals of various kinds. There is also wide agreement that subparts of texts are related to one another in various ways. Understanding these relationships can be seen as an important aspect of having understood a text at all, but linguistic accounts of these uncontroversial phenomena are still limited. Rhetorical Structure Theory (RST) is one of the most significant theoretical and practical advances that has been made in recent times toward making it possible to analyze this kind of structure linguistically. RST seeks to explain the coherence of text by describing how each individual component of a text contributes to the communicative goals of the text as a whole. To do this, RST employs a set of rhetorical relations. These are in principle open-ended, but in practice rather narrowly constrained. An RST analysis, then, progressively deconstructs a text into its smaller component parts. Crucially, because what is being captured is not just a structure but a relationship, each subcomponent itself has (at least) two parts. In every relation, one of the subparts is seen as the most important, or nuclear, component at that level in structure. The other subparts, called satellites, are subservient to the part identified as the nucleus. Each complex of subparts taking part in the relationship is described according to a set of rhetorical relations defined by the theory. A complete analysis then consists of a single hierarchical rhetorical structure defined by rhetorical dependency links between structural siblings and composition between parts and their subparts. The smallest parts of the structure are called units and correspond directly to portions of the analyzed text.

A text is seen to be coherent and 'well-formed' according to RST when it is possible to construct at least one single overarching hierarchical rhetorical structure for the text as a whole. This structure must obey the organizational principles set out by RST, most important of which are the conditions that RST places on the rhetorical relations that must be used to relate contiguous parts of the text, or text spans. Most natural texts will allow at least one complete analysis. Uncovering that analysis – i.e., making the rhetorical relations involved explicit – can be a significant aid toward understanding how the text achieves the effects that it does.

RST has been used successfully for a variety of tasks, ranging from linguistic text interpretation to computational applications in language production and automatic analysis.

The Origins of RST

RST was originally developed during the mid-to-late 1980s by William C. Mann at the Information Sciences Institute of the University of Southern California (USC/ISI) and Sandra Thompson at the University of California at Santa Barbara. Mann was seeking a model of textual coherence sufficiently explicit to drive automatic text production (see Mann and Moore, 1981) and Thompson had been involved with issues of discourse coherence for many years, particularly researching the textual signals of discourse relations. The concerns of Mann and Thompson were combined in the original formulation of RST. Subsequently, further refinements to the theory in relation to its links with other kinds of linguistic description were contributed by Christian Matthiessen (then also of USC/ISI).

Introduction: What is Rhetorical Structure Theory?

Readers feel that natural texts are coherent and well structured, and that texts achieve rhetorical goals of various kinds. There is also wide agreement that subparts of texts are related to one another in various ways. Understanding these relationships can be seen as an important aspect of having understood a text at all, but linguistic accounts of these uncontroversial phenomena are still limited. Rhetorical Structure Theory (RST) is one of the most significant theoretical and practical advances that has been made in recent times toward making it possible to analyze this kind of structure linguistically. RST seeks to explain the coherence of text by describing how each individual component of a text contributes to the communicative goals of the text as a whole. To do this, RST employs a set of rhetorical relations. These are in principle open-ended, but in practice rather narrowly constrained. An RST analysis, then, progressively deconstructs a text into its smaller component parts. Crucially, because what is being captured is not just a structure but a relationship, each subcomponent itself has (at least) two parts. In every relation, one of the subparts is seen as the most important, or nuclear, component at that level in structure. The other subparts, called satellites, are subservient to the part identified as the nucleus. Each complex of subparts taking part in the relationship is described according to a set of rhetorical relations defined by the theory. A complete analysis then consists of a single hierarchical rhetorical structure defined by rhetorical dependency links between structural siblings and composition between parts and their subparts. The smallest parts of the structure are called units and correspond directly to portions of the analyzed text.

A text is seen to be coherent and 'well-formed' according to RST when it is possible to construct at least one single overarching hierarchical rhetorical structure for the text as a whole. This structure must obey the organizational principles set out by RST, most important of which are the conditions that RST places on the rhetorical relations that must be used to relate contiguous parts of the text, or text spans. Most natural texts will allow at least one complete analysis. Uncovering that analysis – i.e., making the rhetorical relations involved explicit – can be a significant aid toward understanding how the text achieves the effects that it does.

RST has been used successfully for a variety of tasks, ranging from linguistic text interpretation to computational applications in language production and automatic analysis.

The Origins of RST

RST was originally developed during the mid-to-late 1980s by William C. Mann at the Information Sciences Institute of the University of Southern California (USC/ISI) and Sandra Thompson at the University of California at Santa Barbara. Mann was seeking a model of textual coherence sufficiently explicit to drive automatic text production (see Mann and Moore, 1981) and Thompson had been involved with issues of discourse coherence for many years, particularly researching the textual signals of discourse relations. The concerns of Mann and Thompson were combined in the original formulation of RST. Subsequently, further refinements to the theory in relation to its links with other kinds of linguistic description were contributed by Christian Matthiessen (then also of USC/ISI).

Table 1 A list of RST relations

Subject-matter relations	*Presentational relations*	*Multinuclear relations*

Volitional cause		
Volitional result		

Mann and Thompson observed that certain sequences of textual material appeared to suggest additional assertions over and above those explicitly made in the text itself (Mann and Thompson, 1986). For example, in the textual sequence in (1), we need to see that the two sentences are related in some way in order to understand why they have been said:

(1) He explains things well. He'll make a good teacher.

In particular, unless we can see that an additional assertion of the form in (1a) is being made, we will not have understood the text:

(1a) Because he explains things well, I think he'll make a good teacher.

What we understand in understanding (1) is that the first sentence is being given as evidence for the statement made in the second sentence.

We can readily find sequences where other relations between the parts need to be posited in order to explain the coherence of combinations of linguistic units. For example, in the text extract in (2), we need to posit a relationship of reason between the two sentences.

(2) The lorry veered off the road. The brakes had failed.

In addition, both of these relationships are quite different from the kind of temporal sequence that we find between sentences in a simple narration. These kinds of relations were identified and catalogued by Mann and Thompson as a move toward understanding how texts 'mean' in addition to the basic or propositional content of the individual sentences, even when there is no explicit linguistic marker of the relation being expressed. These 'implicit assertions' are necessary for both speaker and hearer: a hearer must uncover them in order to understand why sentences are being placed together, and a speaker relies on a hearer uncovering them in order to understand the message.

Figure 1 Symmetric relation: sequence.

These kinds of relationships can hold at any level in the text; they are not exclusively relations between individual sentences. This leads to the necessity for a recursive definition of rhetorical structure – that is, text segments in which rhetorical relations of particular kinds are being employed can themselves, as aggregates, take part in rhetorical structures at higher levels. RST does not relate the individual sentences themselves, but the rhetorical intent of the discourse portions over which the rhetorical relations hold – and this can correspond to individual sentences, units smaller than sentences, and larger units taking in more extensive portions of a text.

Mann and Thompson carried out a detailed examination of the kinds of rhetorical relationships and corresponding rhetorical structures needed to carry out text analysis of texts of any kind. They based this examination initially on a corpus of several hundred texts drawn from a variety of text types. The result was a collection consisting of around 20 relations sufficient for covering the texts they investigated. These relations, now termed classical RST, are set out and defined in detail in several papers, most prominent of which are Mann and Thompson (1986, 1988) and Mann *et al.* (1992). Although Mann and Thompson explicitly stated this list of relations to be open-ended, it has in fact proved very stable over the years. However, occasional evidence has been found for further rhetorical relations that were not included within the original set, and so most researchers now accordingly work with what is called the extended RST set, which now includes around 30 relations. A list of these relations is shown in Table 1.

As intended by Mann, the framework was soon taken up for computational systems, particularly for automatic text generation. The theory has also been taken further by text linguists, who have applied it

Figure 2 Asymmetric relation: enablement.

to a wider range of texts than the original starting point of Mann and Thompson. The extended RST list has also been validated across several languages; contrastive RST analyses have been performed, for example, for Dutch (Abelen *et al.*, 1993), Chinese (Chinese, Mandarin) (Marcu *et al.*, 2000), French, Portuguese, and German (German, Standard) (Delin *et al.*, 1996), Spanish (Taboada, 2004) and a host of other languages. RST therefore continues to be an active area of research into text organization.

Although primarily developed for the analysis of written texts, there have also been attempts to apply RST in the analysis of dialogue (cf. Fawcett and Davies, 1992; Maier and Sitter, 1992; Daradoumis, 1995). Martin (1992) criticized RST from this perspective, arguing that the deep structural embeddings that RST requires do not align well with the kind of clause combining observable in spontaneous speech. This continues to be an active area of debate.

Definitions

We gave an informal indication of the structure of an RST analysis above. We need to refine this somewhat for a full definition of RST. First, there are two kinds of rhetorical relations: asymmetric relations, where one of the related rhetorical units is singled out as the rhetorical head, or nucleus, and symmetric relations, also termed multinuclear, where all of the related units are of equal status. Examples of multinuclear relations are Contrast, which draws a relation between two elements – we cannot say that one of these elements is then more important than the other, it is precisely the function of the contrast to present them both – and Sequence, which orders an arbitrary number of elements in a temporal or other organizational sequence – again, we cannot pick one of these out as being more essential than the others.

In Figure 1, the symmetric relation of Sequence is shown. In this relation, the nuclei have identical status. The notation is standard in RST analysis, showing each relevant text span surmounted by a line showing its extent. The straight lines emerging from the text spans show that each span is analyzed as a nucleus.

The relation in Figure 2, which shows an example of a relation called Enablement, is an asymmetric relationship. The nucleus is still indicated by a straight line – vertical now – while satellites and their link with the nucleus to which they relate are shown by an arc.

The importance of a nuclear element is defined in terms of its contribution to the rhetorical goals of the text as a whole. Within RST, these goals are intended to correspond with the intentions of the speaker. A nuclear element cannot be removed from a text without damaging its coherence, whereas satellites can often be removed without compromising overall coherence (i.e., the text would still be perceived as attempting to fulfill the same broad communicative function).

The rhetorical relations themselves are defined in terms of applicability conditions; these are the rules that make up each relation and form a valuable guide to the analyst in explaining what is meant by each relation and how to select which one to use in a given context. Each relation defines:

- a set of conditions that must hold of the nucleus
- a set that must hold of the satellites
- a set of imputed conditions that must hold of the nucleus and satellite combination
- a specification of the effect that is achieved with the rhetorical relation on the hearer/reader.

The conditions are usually expressed in terms of the beliefs, intentions, and desires of the speakers and hearers. RST also considers the effect intended by the speaker/writer in using a relation.

For a good example of a relation definition, we can revisit the RST relation of Enablement. An example of a minimal text fragment involving Enablement can be seen in the sentence:

(3) Open the doors by pressing the red button.

In (3), the reader is told to do something, but is also told (in the 'by' phrase) how to do it. This is an example of Enablement, which relates the action to be performed to some subsidiary information that enables it (i.e., that makes the performance of the action easier or possible). It would also have been possible to present the information in two wholly separate clauses – 'Open the doors – press the red button.' for example. The relation definition is made up of four slots, as follows:

- Conditions on the nucleus (N): N identifies some action that it is possible for the reader/hearer (H) to perform and which is, at the point in time at which the relation is given, 'unrealized.'

- Conditions on the satellites (S): S identifies some information that improves the H's ability to carry out the action identified in N.
- Conditions on the N+S combination: H comprehending S increases H's potential ability to perform the action in N.
- The effect of the relation: H's potential ability to perform the action in N increases.

Rhetorically, then, Enablement sees the action to be performed as the nucleus and the subsidiary information as satellites. We can see this with the current example by leaving out the enabling information 'by pressing the red button.' The main purpose of the text fragment appears to be that the hearer open the doors; this remains even when the enabling information is omitted. A generally useful way of viewing the nucleus–satellite relationship is therefore to say that the satellites increase the range of situations where the rhetorical force covered by the nucleus will be successful. In the current example, if the hearer knows how to open the doors anyway, then the enabling information may be safely omitted. But in situations where the hearer does not know this, the rhetorical force will fail without the satellites being present.

All of the rhetorical relations employed within RST are defined in this manner. A full list can be found in the definitive report of Mann and Thompson (1988), extracts from which, including the full relation definitions, are given on the RST website (see references). An almost exhaustive survey of the current state of the art in RST, the applications that are being pursued, references to RST analyses for a broad range of languages, as well as discussions of problems and issues, is available in two papers by Taboada and Mann (2005, 2006).

An analyst approaches a text through applying the relation definitions progressively, decomposing the text into ever-finer segments. Which relation to choose is determined by a good understanding of the applicability conditions (the information in the four slots seen above in the Enablement relation). Importantly, the applicability conditions must respect which discourse segments have been selected as nuclear and which as satellites. Sometimes it is possible to find situations where the conditions hold, but the nuclearity assignment would be wrong; this is sufficient to rule out the applicability of the relation considered. Moreover, when combining an RST fragment into a larger structure, it is the effect of the N+S combination that must be taken into consideration as a possible nucleus or satellite for the next level 'up.' In this way, the combination of structures into larger hierarchical structures is made to enforce a rhetorical consistency of purpose for a text as a whole.

The smallest piece of text that can participate in rhetorical relationships, the text span that is the finest level of rhetorical structure, is left open for the analyst to decide. Mann and Thompson deliberately allow this to vary depending on the purposes for which an analysis is undertaken. It may be fixed as sentences, as grammatical clauses, or as entire paragraphs, just as, in grammatical analysis, the analyst can decide how fine he or she needs the analysis to be. For English, a typical analytic decision is that the relations should apply to grammatical clauses but not within clauses. This may not be appropriate for all languages, however, because what may well be a grammatical clause in English could be a smaller grammatical unit in another language. Examples discussed here from the text type of instructions include the following contrasting pair from English and German:

(4a) Twist the top until it locks.
(4b) Drehen Sie den Deckel bis zum Anschlag.

What in the English version appears as a grammatical dependent clause ('until it locks') is in the German version a prepositional phrase ('bis zum Anschlag'). Therefore, either the text spans for the rhetorical analysis must include at least prepositional phrases for German or the two corresponding sentences must receive differing rhetorical analyses – which may be unsatisfactory, given their very similar purpose. The exact positions taken on this issue in the literature vary; an extensive discussion was given by Grote (2004).

There are still many questions concerning how a body of rhetorical relations such as those proposed in RST are to be best identified, defined, and represented. Since the original collection of relations was presented as a simple set, many subsequent researchers concerned themselves with the question of just how large this set might need to become – in one collection, Maier and Hovy (1993) presented over 300 'rhetorical relations' in a classification hierarchy. Moving in the other direction, Sanders *et al.* (1992) focused attention on four contrasting features for describing coherence relations and investigated these in terms of their psychological effects. Combining features then gives rise to particular rhetorical relations. One of these features, which they termed the basic rhetorical relation, concerns causality (i.e., whether two consecutive discourse segments are related in the world by causality or not). Here, Sanders *et al.* were able to demonstrate clear psychological effects that differentiate reliably between several distinct classes of relations. Reliability varied, however, across

Figure 3 RST analysis of recipe for potted cheese.

the features considered, and so further work has subsequently investigated these issues more closely.

RST has been criticized because it only allows one rhetorical relation to hold between discourse segments. Some authors, e.g., Moore and Pollack (1992) and later Maier and Webber and colleagues (Maier, 1996; Webber *et al.*, 1999), argued that this particular RST constraint needs to be relaxed. Moore and Pollack suggested a solution by distinguishing between two main types of relations among those posited by Mann and Thompson – subject-matter and presentational relations. Subject-matter relations are those that take their applicability conditions from the states of affairs being described; presentational relations are dependent on the particular rhetorical argument being pursued by the writer/speaker. Moore and Pollack suggest that these two different types of relation should be allowed to hold at the same time.

In a move in some ways similar to the use of features by Sanders *et al.* mentioned above, Bateman and Rondhuis (1997) argued that rhetorical relations are not atomistic theoretical constructs at all, but bundles of features. They proposed that these features can be drawn from the three kinds of meanings commonly proposed in systemic–functional linguistics (see, e.g., Halliday and Matthiessen, 2004), thereby adding 'textual' meaning (concerned with nuclearity choices) to the 'ideational' (subject-matter) and 'interpersonal' (presentational) meanings already suggested by Mann and Thompson's original account. This solves the multiple simultaneous relations problem by moving simultaneity to the features that hold rather than needing to maintain individual and separate rhetorical relations in the rhetorical structure.

An Example of RST Analysis

In this section, we give a very short worked example of text analysis according to RST. We take a simple recipe as indicative of the kind of analytic decisions and rhetorical relationships employed. The recipe is as follows:

> Potted Cheese
> Beat 225 g mature cheddar cheese and 50 g salted butter with 1 tsp dry mustard so that it forms a stiff cream. Spoon into small ramekin dishes. Cover with 50 g melted butter and refrigerate for 2 hours. When the potted cheese has set, serve spread on brown toast or crackers.

As many recipes do, this recipe consists of a set of sequential steps. These are represented in RST as a Sequence relation. However, there are two steps that are slightly more complex than the others. In the first, a beating action is carried out *so that it forms a stiff cream*. This clause tells the reader why the beating is done, and is recognized in RST as a Purpose relation. In the second, the instruction is to *serve* only *when the potted cheese has set*. Because the *when* clause places a condition on when the action can be done, RST recognizes this as a Condition relation. So as well as

taking part in the Sequence relation, these elements are themselves complex. The diagram in Figure 3 shows the full RST analysis of the recipe text.

Relations to Other Levels of Linguistic Description

RST is intended to cover the domain of linguistic description to do with 'text structure.' However, it is also necessary that this domain be related to other areas of linguistic description. One systematic problem haunting text linguistic accounts of many kinds has been that it is difficult to draw conclusions about what a particular text structure says about possible or impossible grammatical, lexical, and semantic expressions. This also has repercussions for the reliability of a text analysis; if it is not possible to state the observable linguistic signs of a text structural analysis, then it is possible to suggest several plausible analyses and hard to decide between them. RST does not position itself on this issue particularly clearly. While it is possible to posit a rhetorical relationship between elements without any supporting linguistic marker such as a discourse connective, it is much clearer positive evidence for a relation if an explicit marker is present.

In some cases at least, enough explicit evidence can be gleaned from texts to allow an RST analysis to be produced automatically. Marcu (2000a) followed this approach in considerable detail. Speakers also give explicit intonational signals that correspond to quite subtle distinctions in the rhetorical structure – in particular to structural embedding and nuclearity (see den Ouden, 2004). Nevertheless, it seems unlikely that fully automatic RST text analysis can ever be infallible. RST analysis explicitly draws on judgments of intention and belief, and reasoning about these is notoriously difficult to do automatically.

There are also situations where an RST analysis overlaps with analyses at other levels of linguistic description. For example, whenever an RST analysis is suggested for combinations of clauses, the relationships involved might also be described purely on the basis of grammar. For example, what, in RST terms, might be considered a Purpose relationship between a rhetorical nucleus and a satellite might, in terms of grammar, be seen as a purposive adverbial clause. There is probably little sense in asking which of these analyses is the 'correct' one; it simply depends what the analysis is trying to achieve. The fact that structural signaling can take place at either level has been studied in detail for clause combining by Matthiessen and Thompson (1989). The relationship with lower levels of grammatical structure may also be considered: Martin (1992) looked at how conjunctive semantic relations find linguistic realizations inside clauses and even within nominal and prepositional phrases, while Bateman and Rondhuis (1997) looked at the relationships between differing levels of abstraction in rhetorical organization in general.

Sometimes when an RST analysis is possible, it still seems less than useful to do so. An example offered by Mann and Thompson is that of analyzing a letter. There are segments of the letter, such as the address of the addressee, that of the sender, the date, the place where it was written, the salutation ('Dear Ms Smith'), the sign-off ('Yours in haste'), etc., which are normally part of letters but whose rhetorical linkage is weak. One could provide a rhetorical analysis, but for the most part it seems more appropriate to describe the textual structure involved as a generic structure for this particular text type. As such, it is similar to a partly frozen idiom that allows only limited innovation; the original rhetorical motivations (if any) of the organization have been lost, and one is left with a generic template of how instances of such text types are constructed.

The benefits of RST analysis obviously diminish progressively as one moves away from the central area for which RST is intended to operate. Carrying out analysis in terms of RST and other levels of description may, however, be useful when we are considering aspects of linguistic change, of the emergence of new grammatical configurations or generic text structures. Here, the kind of motivations that we obtain from the rhetorical level of description can indeed be useful indicators of reasons for change.

Applications of RST

As explained above, the first application of RST was in computational linguistics. Mann had been searching for an account of text structure that would be amenable to computational formalization, and with RST he succeeded. Two approaches to automatic text generation using RST were developed independently at the Information Sciences Institute; one by Hovy (1988) was essentially bottom-up, in that a collection of data was 'structured' in order to produce a well-formed RST tree; the other, developed by Moore and Paris (1988), interpreted the applicability constraints in the RST relation definitions as plan operators, i.e., methods for achieving goals that could be performed using the top-down hierarchical planning paradigm well-established in Artificial Intelligence (AI; see Sacerdoti, 1973). A detailed description of these uses of RST was given by Hovy (1993), while computational introductions were given, for example, by Bateman and Zock (2003)

and Vander Linden (2000). Essentially, production of a text starts with a communicative goal to be achieved, and the planning process successively refines this goal according to a library of plans into 'smaller' goals until an appropriate granularity for expression through rhetorical relations and unitary propositions is reached. The result is then a completed RST tree with constraints attached to all the leaves concerning the content and form of the linguistic material that is to be generated there, resulting in a specification for a well-formed text that realizes all the rhetorical goals. The approach was subsequently adopted in several large-scale natural language generation projects and for several languages (see, e.g., Rösner and Stede, 1992; Delin *et al.*, 1994); multilingual results have also fed into new accounts of contrastive pragmatics (Delin *et al.*, 1996).

RST subsequently became the approach to text planning most widely adopted in automatic text production but was not considered for text interpretation due to the perceived subjectivity – and therefore unreliability – of RST analyses. This changed substantially with the work of Marcu and colleagues (Marcu, 2000a; Marcu *et al.*, 2000), which sought to produce RST analyses of text automatically, drawing on a broad basis of surface linguistic cues. This could then be used for summarization of texts in the manner suggested by O'Donnell (1997), where successively removing deeply embedded satellites naturally results in shorter texts without impairing text coherence. Marcu (2000b) provides a book-length discussion of the issues and methods of RST-based automatic summarization and some of the problems of the approach.

A further development arising out of the use of RST for automatic text production was the extension to consider the creation of multimodal documents. The underlying intuition here is that, just as segments of a text contribute to that text's coherence in systematic and specifiable ways, segments of a multimodal document, involving pictures, diagrams, and texts, could also be related in an analogous manner. Such an extended RST approach involving relationships between text, diagrams, and pictures was set out by André and Rist (1993). This basic approach was subsequently adopted by a number of researchers and also used for computational implementations of document production systems. Perhaps surprisingly, little of the original RST specification needed to be changed in these efforts, although some more recent and detailed investigations of the differences between RST for texts and RST for multimodal documents have modified this view somewhat. Bateman *et al.* (2004) showed, for example, that it is necessary both to extend the kinds of relations that are involved when we are relating parts of a document that are realized in different 'modes' and to consider the influence of the (at least) two-dimensional representational medium (e.g., the page or screen) rather than the one-dimensional medium of language assumed by RST (see also Henschel, 2002). Applications for the analysis and critique of multimodal documents, particularly of page layout and design, are one result of such studies (Delin and Bateman, 2002).

A further and very recent proposal for an application of RST is for driving speech synthesis. In a series of detailed empirical studies, den Ouden (2004) shows that fine details of intonational delivery of texts read aloud correlate significantly with the RST analyses of those texts. These details include speed of delivery as well as intonational phrasing. It is then suggested that incorporating a responsiveness to the RST structure of a text would contribute to the naturalness of any synthesized speech for the text.

Finally, RST also continues to be influential both in linguistic approaches to investigations of text structure and in psycholinguistic attempts to validate or refine such approaches. Particularly important for the former are approaches that combine RST with aspects of information structure (Chiarcos and Stede, 2004; Taboada, 2004) and with interclausal coherence/cohesion when linearising a rhetorical structure in text (Bateman, 2001). For the latter, RST has offered a number of variables for more systematic investigation: nuclearity, structural embedding, and type of rhetorical relation are all clear claims of an RST analysis that can be subjected to empirical study. A range of investigations and theoretical discussion are presented by den Ouden (2004).

Compared with more traditional text linguistic approaches to describing and motivating text structure, RST can be distinguished by the detail given both to the methodology pursued when constructing an analysis and to the level of detail of the resulting analyses. The definitions of the individual rhetorical relations and the structural schemata in which they can be embedded significantly constrain analysis results. In studies carried out by den Ouden and colleagues (den Ouden *et al.*, 1998; den Ouden, 2004) it has been found that trained annotators reliably produced compatible RST analyses independently of one another; the rhetorical structures produced agreed most with respect to their segmentation and attribution of nuclearity, and less concerning the identity of individual relations. Detailed combinations of RST with other, more recent and formally specified

linguistic approaches to text organization such as Asher and Lascarides's Segmented Discourse Representation Theory (SDRT; Asher and Lascarides, 2003) or Discourse Tree Adjoining Grammars (e.g., Webber *et al.*, 1999) remain to be done but would no doubt be highly beneficial for subsequent research in text structure in general.

Rhetorical Tropes in Political Discourse

M Reisigl, University of Vienna, Vienna, Austria

© 2006 Elsevier Ltd. All rights reserved.

Classical Rhetorical and Actual Characterization of Tropes

The Greek substantive 'tropós,' originally meaning 'turn' or 'direction,' is derived from the verb 'trépein,' which signifies 'to turn (over/round).' The classical rhetorical term encompasses all figures of speech that involve a turn of meaning (i.e., a linguistic transference from one conceptual sphere to another). Conventionally, tropes are considered to be conventionalized means of expression of so-called 'improper speech' or 'nonliteral speech,' which is characterized by a (poetically) licensed difference between the 'ordinary' literal and the 'extraordinary' intended meaning of a speech. This tropological theory of deviation

or substitution is nowadays often criticized for mistakenly assuming that tropes are deviations from linguistic normality and can thus simply be replaced by 'proper' expressions or phrases. However, tropes are, in fact, very common in 'everyday language,' and there is no such thing as an original *verbum proprium* or *substituendum* that perfectly corresponds to the trope (cf., among others, Kienpointner, 1999: 66–68).

In contrast to other figures of speech (e.g., figures of repetition like anaphora, epiphera, alliteration, assonance, consonance, and parallelism), tropes are said to be more closely related to content than to form or structure. Concerning the relationship between what is said or written and what is meant, Heinrich Lausberg (1990a: 64–79) distinguishes between two types of tropes.

Tropes of shifting boundaries ('Grenzverschiebungstropen') consist of moving the borders of neighboring semantic fields or the borders within one and the same semantic field. These tropes are determined by a relationship of inclusion or (factual) contiguity between what is said or written and what is meant. They are, accordingly, divided into two subcategories. Periphrasis, litotes, hyperbole, emphasis, antonomasia, and synecdoche are assigned to the first subcategory. They are constituted by shifting the boundary within a semantic sphere. The second subcategory involves a relationship of adjacency. It is prototypically represented by metonymy.

The second type of tropes is labeled 'leaping tropes' ('Sprungtropen'). In comparison to tropes that involve shifting boundaries, leaping tropes are grounded on a 'leap' from one semantic sphere to another sphere that is not adjacent to the first one. Traditionally, metaphor, allegory, and irony are taken as leaping tropes. Their intended meaning is to be found in a semantic domain that clearly differs from what is actually said or written. In concrete rhetorical analyses, a neat distinction between the two types of tropes – as well as between the single tropes allocated to these two types – is not always feasible, as simultaneous tropic membership of specific linguistic realizations is not unusual (see Fontanier, 1977; Morier, 1989; Lausberg, 1990a, 1990b; Groddeck, 1995; Plett, 2001, for various proposals to classify tropes; see Goossens, 1995, for multiple tropic membership, discussed with the example of 'metaphtonymy,' the simultaneous combination of metaphor and metonymy).

Antique rhetoric ascribes primarily an ornamental function to tropes. It considers them to be deviations from ordinary language for the sake of adornment. This view of tropes as purely decorative linguistic appendices that are 'added' to the linguistic raw material in the rhetorical production stage of elocution to give glamour to one's speech has widely been overcome by a reassessment that sees language as basically tropic. Nowadays, it is almost commonplace in modern rhetoric, linguistics, language philosophy, and cognitive science that all areas of language are pervaded with tropes, and that tropes, like metaphors, metonymies, and synecdoches, function as elementary cognitive principles that – often unconsciously – shape and structure human perception and thinking. Tropes are no longer exclusively associated with the stage of elocution; rather, they are also related to the stage of *inventio* and, of course, to processes of the speech's reception or apperception.

Political Discourses

The contention of the tropes' pervasiveness in language holds also for the realm of political language, which – generally speaking – evolves in a tension between the preservation and transformation of power relations, public decision making, and problem solving, as well as political order. Many names of political institutions and 'collective' political actors have their origin in metaphorization and metonymization (e.g., 'government,' 'parliament,' 'minister,' and 'ministry'). Political discourses are full of tropes related to the three political dimensions of form (i.e., polity, the basic order related to political norms, institutions, system, and culture), content (i.e., policy, the policy-field-related planning and acting concerning the identification of political problems, the development and implementation of political programs, and the evaluation and correction of their implementation), and process (i.e., politics, the political competition related to the conflicts between political actors and to the achievement of followers and power). In all fields of political action – within and across which discourses manifest themselves – politicians employ these figures of speech as effective rhetorical means of constructing, representing, and transforming political 'reality,' as well as a means of political persuasion.

'Fields of action' (cf. Girnth, 1996) may be understood as "places of social forms of practice" (Bourdieu, 1991: 74) or, in other words, as frameworks of social interaction (Reisigl, 2003: 148). The spatiometaphorical distinction among different fields of action can be understood as a differentiation between various functions or socially institutionalized aims of discursive practices. Among the political fields are the law-making procedure; the formation of public attitudes, opinions, and will; the party-internal formation of attitudes, opinions, and will; the interparty formation of attitudes, opinions, and will; the organization of international and (especially) interstate relations; political advertising; the political executive and

administration; and the various forms of political control (for more details, see Reisigl, 2003: 128–142). A political 'discourse' about a specific topic may have its starting point within one field of action and proceed onward through another one. In this respect, discourses and discourse topics 'spread' to different fields and discourses. They cross between fields, overlap, refer to each other, or are in some other way sociofunctionally linked with each other (Reisigl & Wodak, 2001: 36 f.).

In the given context, 'discourse' is to be seen as topic-related concept that, among others, involves argumentation about validity claims such as truth and normative validity, as well as pluri-perspectivity constituted by the discursive participation of various social actors who assume different points of view (Reisigl, 2003: 92; for a mono-perspectivist conceptualization of 'discourse,' see Fairclough, 1995: 14). Discourses represent semiotic social practices that are both socially constitutive and socially constituted. A political discourse about a particular topic can be understood as a complex bundle of simultaneous and sequential interrelated linguistic acts. These manifest themselves within, and across, the above-mentioned fields of political action as thematically interrelated and problem-centered semiotic (e.g., oral or written) tokens, very often as 'texts' that belong to specific semiotic types (i.e., textual types or genres), which serve particular political purposes (see Reisigl & Wodak, 2001: 36).

Rhetorical tropes fulfill many different purposes in political discourses, especially in regard to positive political self-presentation and negative political other-presentation. With respect to the ideational metafunction of language, these tropes help to 'invent' or construct a political 'reality' (e.g., via incorporating metaphors or allegories like the boat or ship metaphor/allegory, referring to a state), to reduce complexities by simplistic categorization and imaginary representation of political 'reality' (e.g., via color metaphors referring to alleged human 'races'), to vivify, personify, and illustrate abstract or unclear political ideas (e.g., via personifications and other animalizing metaphors), to selectively foreground specific traits of political entities or 'reality' sectors (e.g., via particularizing synecdoches), and to background or hide specific political aspects, actors, or actions (e.g., via metonymies that represent persons by place names).

With respect to the interpersonal metafunction of language, these tropes are employed to promote the identification with single or 'collective' political actors (e.g., leaders, parties, states, or nations), as well as with their political aims and ideologies (e.g., via the heart metaphor relating to a specific nation-state within a confederation of states); to promote in-group solidarity (e.g., via family or kinship metaphors, such as the androcentric metaphor of brotherhood), referring to the imagined community of a nation or of politically united nations; to support out-group segregation and discrimination (e.g., via deprecating animalizing metaphors like parasite, rat, and vermin); to create a feeling of security by suggesting stability and order (e.g., via construction metaphors like house, referring to a state); to create a feeling of insecurity by suggesting chaos, disorder, danger, and threat (e.g., via flood or wave metaphors referring to immigrants); to justify, legitimize, or delegitimize specific political actions or their omission (e.g., via metaphors of gain or cost relating to the consequences of a specific action or omission of action); and to mobilize political followers to perform specific actions which can culminate in physical or military aggression, such as war (e.g., via instigating militarizing metaphors or rape and monster metaphors relating to 'the enemy'). Some of these functions will be elaborated on in greater detail in the following section.

Toward a Tropology of the Political

For a long time, analysis of political language has merely been carried out as a side job both on the part of political scientists interested in issues of language and on the part of linguists interested in political issues. As a consequence, the respective studies in linguistics and political science have frequently been amateurish with respect to theory, methods, and methodology. This critique also relates to the study of tropes in political discourses. Linguistic, and especially rhetorical, approaches often have suffered from politological ignorance and did not venture beyond a positivist identification and enumeration of figures of speech, as well as a very general characterization of the persuasive or manipulative potential of single tropes, especially of metaphors. The analyses of tropes in political science did, however, often not exceed everyday linguistic triviality when selectively looking at 'linguistic images' with political significance.

A remedy for the many shortcomings in the area can be found in a transdisciplinarian politolinguistic approach that tries to connect and synthesize rhetoric, linguistic discourse analysis, and political science. Such an approach should theoretically rely on actual concepts in political science, as well as on rhetorical and discourse analytical categories such as those outlined in the 'Classical Rhetorical and Actual Characterization of Tropes' and 'Political Discourses' sections. With respect to the topic in question,

politolinguistics should build a 'tropology of the political' (i.e., a theory of tropes that systematizes and explains the political and linguistic functions or purposes of tropic language in polity, policy, and politics; for a first sketch, see Reisigl, 2002, and Reisigl, 2003: 237–258). In what follows, this tropology is outlined with the example of three of the four so-called 'master tropes' (see Burke, 1969: 503–517); that is to say, with the example of metaphor (including personification and allegory, the latter being conceived as continuous, expanded metaphor), metonymy, and synecdoche (including antonomasia as a special form of synecdoche). The fourth alleged 'master trope,' irony, will be dropped, as its character is very different from that of the three basic tropes. In contrast to metaphor, metonymy, and synecdoche, irony is much more heterogeneous. It often involves the prosodic, gestural, or facial-expressive dimension of language, which enables one to recognize that what has been said is not to be taken literally, but ironically. To explicate the complex character of irony would go beyond the scope of this introductory article.

In addition, in the present context, for reasons of limited space, no attention can be paid to other linguistic occurrences traditionally also apostrophized as 'tropes.' Periphrasis, litotes, hyperbole, and emphasis are – as is irony – much more heterogeneous than metaphor, metonymy, and synecdoche. As rhetorical phenomena, they do often derive from the three basic tropes or manifest themselves in manifold tropic ways. Periphrasis, for instance, can linguistically be realized as antonomasia (which is characterized as a descriptive phrase standing for an individual to be identified with a proper name or, conversely, as a proper name standing for a general character trait), synecdoche, etymology (which is based on the principle of 'nomen est omen'), metaphor, allegory, metonymy, euphemism, *descriptio* and *definitio*, and so forth (Plett, 2001: 91). However, some of these other 'tropes' frequently involve linguistic dimensions that are not genuinely related to tropes, such as the so-called 'trope of emphasis,' for example, which comprises numerous phonological, morphosemantic, and syntactic characteristics that are not to be seen as tropic qualities (Reisigl, 1999: 197–199). To take into consideration all these various aspects and their complex interplay would be beyond the scope of this overview.

Metaphors

Of all tropes, metaphors certainly receive the most attention in the analysis of political discourses. Many studies have been carried out in the last decades that focus on metaphorical speech in different political and historical contexts (cf., among many others, Lakoff, 1991, 1992; Chilton & Ilyin, 1993; Chilton & Lakoff, 1995; Schäffner, 1995, 2002; Chilton, 1996; Semino & Masci, 1996; Böke, 1997, 2002; Musolff, 2000; El Refaie, 2001; Klein, 2002; Panagl & Stürmer, 2002; Stürmer, 2002).

Theoretically, metaphors can be understood as 'impertinent predications' (Ricœur, 1986), in the sense that an expression is semantically incompatible with the context of meaning in which the expression is uttered. Metaphor establishes a similarity between two different semantic domains. As it "is a device for seeing something *in terms of* something else" (Burke, 1969: 503), it is most closely connected with the question of perspectivation.

Many different types of metaphor occur in political discourses. Some metaphors transform inanimate 'objects' into animate ones, whereas others transform animate 'objects' into inanimate ones. Some metaphors predicate onto animate 'objects' the quality of other animate 'objects,' whereas others predicate onto inanimate 'objects' the quality of other inanimate 'objects.' Some transform abstract entities into concrete ones that are sensually perceivable, and others merge different human senses synesthetically or into catachresis (cf. Plett, 2001: 101–104). Many metaphors in political discourses transfer aspects from the economic to the political domain, and many from the domain of private life and family life onto public life and 'collective actors.' Various metaphors project elements from the domains of sports onto the political domain. All these and many other metaphorical types (including those that will be mentioned in the following explications, which for the most part are also to be found in Reisigl & Wodak [2001: 58–60]), should be taken into consideration by an elaborated phenomenology of metaphors in political discourses.

Personifications or anthropomorphizations are metaphors that bring together and link two different semantic fields, one with the semantic feature (−human), the other bearing the semantic feature (+human) (cf. Lakoff & Johnson, 1980: 34). Personifications are rhetorically used to give a human form, to humanize inanimate objects, abstract entities, phenomena, and ideas. They play an important role in animating imagined 'collective subjects' – as, for example, 'races,' 'nations,' 'ethnicities,' 'states,' 'state unions,' and many other political 'collective' actors (cf. Goodwin [1990] for the question of 'engendered' nations). Their apparent concreteness and vividness often invites hearers or readers to identify or to feel solidarity with or against the personified political entity.

In addition to personifications, there are many other forms of metaphors that are important in referentially and predicationally constructing in-groups and out-groups in politics and polity, whether they are imagined as 'races,' 'nations,' 'ethnicities,' 'states,' and 'tribes' or as specific 'racialized,' 'national,' 'ethnic,' or 'religious' majorities or minorities. Many of these metaphors function as 'collective symbols.' Very often, they are simultaneously used both as metaphors and representative synecdoches (cf. Gerhard & Link, 1991: 18).

In discourses about 'races,' 'nations,' and 'ethnicities,' these metaphors and synecdoches, but also the respective metonymies, are almost always connected with specific dychotomic, oppositional predications that can form networks of semantic isotopes that help politicians to polarize and divide the world of social actors into 'black and white' and into 'good and bad.' The most frequent and conspicuous of these predications to 'real' or imagined social actors and political systems that serve positive self-presentation and negative other-presentation are those of singularity/uniqueness/distinctiveness or individuality, of identity or similarity, of collectivity, of difference, of autonomy/independence, of heteronomy/dependency, of continuity, of discontinuity, of (social) inclusion, of integration, of union or unity, of (social) cohesion, of (social) exclusion, of fragmentarization, of multiplicity, and of dissolution.

Apart from these rather abstract identity-related attributions realized by metaphors, 'national,' 'racial,' and 'ethnic' stereotypes or 'characters' are predicated on the basis of metaphors, relying on the collective symbolic concepts of materiality and body; of material status (e.g., the thermostatic status of 'warm' versus 'cold') and states of matter (solid, fluid, and gaseous); of material qualities like weight ('heavy' versus 'light'); of spatiality, spatiodynamics, and temporality ('fast,' 'fast-moving,' 'ephemeral,' 'persistent,' 'tenacious,' 'lively,' 'mobile,' 'flexible,' 'slowly,' 'inert,' and 'lethargic'); and of the five sensorial concepts of visuality ('fair,' 'pale,' 'clear,' and 'transparent' versus 'dark,' 'gloomy' 'obscure'), audibility ('harmonious' versus 'loud' and 'noisy'), tactile sensation ('hard' versus 'soft'), olfactority ('nice-smelling' versus 'stinking'), and taste ('tasteful' versus 'tasteless').

Racializing, nationalizing, and ethnicizing metaphors of spatiality are primarily ordered around the symbolically and evaluatively loaded binary oppositions of 'internal' versus 'external' or 'internality' versus 'externality,' of 'height/top' and 'up' versus 'bottom' and 'down/low,' of 'foundations/ profundity/ ground' versus 'bottomlessness,' of 'superficiality' and 'flatness' versus 'depth,' of 'center' versus 'periphery/margin,' and of 'boundary,' 'limit,' and 'extension/expansion' and 'spreading' (see Mayr & Reisigl, 1998).

Metaphors of 'racial,' 'national,' and 'ethnic bodies' and 'materiality' are often also derived from naturalizations; that is, from meteorologizations, geologizations, and biologizations. To the latter belong, in addition to the personifications already mentioned (both nongendered and gendered), animalizations (of both sexes) and florizations.

Taking the example of German and Austrian discourses about migrants and 'racialized,' 'national,' and 'ethnic' minorities, the most frequent and stereotypical metaphors employed in the negative construction or identification of social actors and in the negative predicational qualification of them, of their migration, and of the alleged effects of immigration are the following (see Böke, 1997, 2002; Gehard & Link, 1991): *natural disasters*: immigration/migrants as avalanches or flood disasters; *dragging/hauling*: illegal immigration as dragging or hauling; *water*: immigration/migrants as a water-course/current/ flood that has to be 'dammed'; *fire*: alleged effects of immigration/conflicts between 'racialized, 'nationalized,' or 'ethnicized' groups' as a smoldering fire; *thermostatics*: effects of immigration as pressure within the pot and conflicts between 'racialized, 'nationalized,' or 'ethnicized' groups' as bubbling; *plants and fertile soil*: migration and effects of migration as transplantation/repotting,' uprooting, (alleged) causing of social conflicts as seeding; *genetic material*: cultural and social traditions and 'heritage' as genetic material; *growth/growing*: increasing immigration and increasing conflicts as growing; *pollution and impurity*: intergroup contacts, exchanges, and relations as pollution and impurity; *melting*: intergroup contacts, relations, exchanges, and assimilation as melting; *body*: 'racialized,' 'nationalized,' 'ethnicized' groups are metaphorically ascribed 'collective (racial, national, ethnicity) bodies,' outgroups are metaphorized as 'foreign bodies' or alien elements; *blood*: immigration as bleeding white or bloodletting of the imagined 'collective bodies,' intergroup relations as blood impurity; *disease/infection*: immigration/migrants as an epidemic, intergroup contacts and relations as an infection; animals/animal-owning: immigrants/minorities as parasites, as 'attracted like the moths to a flame,' as herded together; *war/fight/military*: immigration as military activity/invasion; *goods/commodities and exchange of goods*: migration as import and export of workers/workforce, migrants as 'freight'; *food*: 'good/ welcome immigrants/minorities' versus 'bad/ unwelcome immigrants/minorities' metaphorized as the wheat that has to be separated from the chaff;

vehicle/boat/ship: effects of immigration as overcrowded boat; and *house/building/door/gateway/bolt*: the ingroups' (e.g., 'national') territory as house or building, and stopping immigration as bolting the door. All of these metaphors are employed in discourses about migrants and migration as implicit argumentation schemes (i.e., as implicit and often fallacious conclusion rules that serve to legitimise discrimination; cf. Pielenz, 1993). The persuasive function of these metaphors may be exemplified with the metaphors of avalanches and flood. The two metaphors suggest that 'If something (e.g., immigrants) is an avalanche or flood, it should be avoided or prevented.' The implicit argumentation function of all the above-mentioned conceptual metaphors is explicable by corresponding if-then schemes.

The suggestive force of metaphors can be so strong as to motivate metaphorologists like Lakoff to contend that 'metaphors can kill' (Lakoff, 1991). In view of animalizing metaphors such as 'rat,' 'parasite,' and 'vermin,' referring to Jews during the National Socialist dictatorship, and implying that if somebody is a harmful vermin, rat, or parasite, he or she should be exterminated, such a metonymical assertion does not appear to be an exaggeration.

The tension between the preservation and transformation of political order, problem-solving, and power relations becomes clearly manifest in the area of metaphorical language. Just to offer a few hints: static metaphors, metaphors of incorporation as well as space and container metaphors seem to be favored if questions of polity, policy, and politics are a matter of consolidation and preservation, whereas destructive and (re)building metaphors, as well as dynamic metaphors (e.g., metaphors of movement and journey), indicate (intended) political transformation. Metaphors with negative connotations implying standstill are employed to evaluate preservation negatively (e.g., 'fossilization of political structures'). Metaphors with negative connotations implying political change are employed to evaluate transformation negatively (e.g., 'dismantling of political infrastructures').

Metonymies

Metonymies (from the Greek: 'renaming,' 'name change') are constituted by a shift involving two semantically (and materially, causally, or cognitively) adjacent fields of reference: a name of a referent stands for the name of another referent, which semantically (abstractly or concretely) adjoins the referent of the name (cf. Morier, 1989: 749–799; Lausberg, 1996: 292–295; Groddeck, 1995: 233–248; Plett, 2001: 98–100).

Depending on the relationship between the two neighboring conceptual fields, one can, among other things, distinguish between the following metonymies: (1) the name of a product or effect stands for the cause or author/creator ('The racist book [standing for its author] provoked many enraged reactions.'); (2) the name of a cause or author/creator stands for the product or effect ('The new Clinton [standing for the new book authored by Clinton] is a best-seller.'); (3) the name of an object stands for the user of the object ('The cars [standing for their drivers] pollute and endanger the environment more and more.'); (4) the name of a container stands for the container's content ('Bush used to drink several glasses [standing for the alcoholic liquid the glasses were filled with] every day.'); (5) the name of a place (e.g., a state/country, town, city, district, or village) stands for the person or persons living at the place ('Italy is not willing to accept more refugees.'; 'Haider says what Austria thinks.'); (6) the name of a building stands for the person or persons staying, working, imprisoned, and so forth, there ('The White House decided to attack Iraq.'; 'The concentration camp Dachau was liberated in 1945 on May 2nd.'); (7) the name of a place stands for an action performed at the place or an event located at the place ('Auschwitz must never ever happen again.'); (8) the name of a person stands for the country or state in which the person is living ('Cooperation is important because we are too small to allow disharmony in vital areas of our country.', as the former Austrian foreign minister, Wolfgang Schüssel, said on 15 May 1995, in his speech commemorating the fiftieth anniversary of the signing of the international 'Austrian State Treaty.'); (9) the name of a person or of a group of persons who have lived in the past stands for a person or a group of persons who are living in the present ('We already fought against Prussians' imperialism centuries ago.'); (10) the name of a time, time period, or epoch stands for the persons living in the time, time period, or epoch ('The twentieth century has seen the most extreme political developments in human history.'); (11) the name of an institution stands for (responsible) representatives of the institution ('The government proposes a more restrictive asylum act.'); (12) the name of an institution stands for actions performed within the institution or events that take place in the institution ('The Second Austrian Republic has almost always been described as a history of successes.'); and so on.

As one can see from examples 1, 3, 5, 6, 7, 10, 11, and 12, metonymies enable speakers and writers within all of three political dimensions to conjure away responsible, involved, or affected actors (whether victims or perpetrators) or to keep them in

the semantic background. Example 9 illustrates how a nationalist identification with the past manifests itself by the usage of the 'historical we.' Example 2 realizes the strategy of metonymic personalization, which aims to stress the focus on a single politician. Example 8 illustrates the strategy of metonymic concretizing and personifying (please note the doubled tropic membership) that aims to promote political identification and solidarity. Example 4 finally shows a very conventional type of metonymy, which in the specific context, could also be read as euphemistic circumlocution of Bush's former alcoholism.

Metonymies of the type 'place name for persons' seem to be among the most frequent ones in political discourses. They often realize the strategy of presupposing intragroup or intra-'collective' sameness or similarity (see Wodak *et al.*, 1999: 43). Such an assimilating or homogenizing function is, however, also fulfilled by synecdoches and specific metaphors.

Synecdoches

Synecdoches (from the Greek: 'understanding one thing with another') are turns of meaning within one and the same semantic field: a term is represented by another term, the extension of which is either semantically wider or semantically narrower (cf. Morier, 1989: 1159–1175; Lausberg, 1990b: 295–298; Zimmermann, 1989; Groddeck, 1995: 205–220; Plett, 2001: 92–94). According to the direction of representation, two types of synecdoches are distinguished (cf. Plett, 2001: 92–94).

The particularizing synecdoche is constituted by a representative relation that consists of a semantically broader concept standing for a semantically narrower concept. The three main subcategories of this type of synecdoches are *pars pro toto* (i.e., the part stands for the whole: 'Hitler [representing Nazi Germany] was finally defeated.'), *singularis pro plurale* (i.e., the singular stands for the plural, forms a 'collective singular': 'The Swiss is industrious.'), and *species pro genus* (i.e., the species stands for the genus: 'The refugee doesn't have a penny to her name ['penny' stands for 'money'].').

The generalizing synecdoche is established by a semantically broader concept that represents a semantically narrower one. The three principal subcategories of generalising synecdoches are *totum pro parte* (i.e., the whole stands for the part: 'Denmark is world champion.' [this synecdoche is also a metonymy]), *pluralis pro singulare* (i.e., the plural stands for the singular: 'We [representing a single person like a queen or a state's president; cf. *pluralis maestatis* or *pluralis modestiae*] hereby enact a general amnesty.'), and *genus pro specie* (i.e., the genus stands for the species: 'Mankind has not learnt anything from history.').

In political discourses, the particularizing synecdoche, just like the generalizing synecdoche, is a means of referential annexation, assimilation, and inclusion. Particularizing synecdoches like the 'foreigner,' the 'Jew,' and the 'American' serve stereotypical generalization and essentialization, which refer in a leveling manner to a whole group of persons. In languages like German, Italian, and French, these are almost always realized in their masculine grammatical form.

Lakoff & Johnson (1980: 38) have introduced – as a special conceptual synecdoche – the synecdoche of the 'controller for controlled' type –, in which leaders, people in power, rulers, and so on stand for the persons who are actually carrying out an action (e.g. 'Bush bombarded Baghdad.'; see also the first synecdoche example). The use of this form of particularizing synecdoche is a central feature of all 'monumentalist historiography' (Nietzsche, 1985) that hides social actors behind their leaders if speakers and writers judge them to be historically insignificant. Even if one does not assume, as do Lakoff and Johnson (1980), that the synecdoche is a special form of metonymy, it seems equally plausible to allocate the type 'controller for controlled' to the category of metonymy.

The crucial role of synecdoches in polity, policy, and politics has not yet been recognized adequately, even though there are first attempts to grasp the political relevance of this trope (see, for instance, Palonen [1995], who analyses party names like 'The Greens' as synecdoches), and even though Kenneth Burke stated more than 35 years ago that every act of social representation and every theory of political representation involves the trope of synecdoche, if "some part of the social body (either traditionally established, or elected, or coming into authority by revolution) is held to be 'representative' of the society as a whole" (Burke, 1969: 508).

Burke's observation may serve as a starting point for a general conceptualization of the relationship between synecdoche and political representation. Synecdochic representation is a basic political principle wherever more stands for less, or less stands for more. Several factors determine whether or in what way a political system of representation is organized democratically: Who is entitled to be a political representative, and who decides on the question of who

will be a representative (active and passive right to vote)? What does the procedure of political authorization to be a representative look like (direct or indirect democracy)? Under which conditions and when can the relationship of representation be dissolved or confirmed (representation for a set time)? To what extent are representatives bound to those who are represented (free or imperative mandate)?

There are different levels of political representation, which can be differentiated when looking at political systems. On the highest level, there are to be found, according to the political system, imperators, kings and queens (monarchy), states' presidents and chancellors (republic and democracy), or dictators (totalitarian dictatorship). Depending on the level of representation, one and the same politician is more or less representative. That is to say, at a lower level of integration, a politician (e.g., a party leader) may represent all members of a specific group or political organization, whereas she or he just represents a minority at a higher level of the system (e.g., in the case that the party is a very small one). These dynamics become very complex in modern democracies, and all the above-mentioned determinants have to be taken into consideration by a tropological model of political representation (for more details, see Reisigl, 2003: 252–258).

Until now, an elaborated tropology of the political does not yet exist, although a developed politolinguistic theory of tropes that scientifically and fruitfully connects rhetoric, linguistic discourse analysis, and political science is an urgent desideratum. Only such a transdisciplinarian approach is capable of systematizing and explaining the many different political and linguistic functions of tropic language in polity, policy, and politics in a differentiated way that does justice to the complex topic in question.

Rhyme

K Hanson, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The *Concise Oxford English Dictionary (COED)* defines 'rhyme' as "identity of sound between words or verse-lines extending from end to last fully accented vowel." The final words of the final couplets in (1) and (2) from Shakespeare's *Sonnets* are thus examples (1) of a 'masculine' rhyme because it involves just one syllable, and (2) of a 'feminine' rhyme because it involves two (with three and even four syllable rhymes also being possible, though unnamed by any gender):

(1) For thy sweet love rememb'red such
wealth brings,
That then I scorn to change my state with
kings. (29, 13–14)

(2) But day doth daily draw my sorrows longer,
And night doth nightly make grief's length
seem stronger. (28, 13–14)

The entry also lists the idiomatic phrase 'imperfect rhyme', and illustrates it with the rhyme of *love* and *prove*, also found as a final couplet in Shakespeare's *Sonnets*:

(3) But since he died and poets better prove,
Theirs for their style I'll read, his for his
love. (32, 13–14)

Finally, the dictionary entry adds that in English prosody specifically, the identity cannot extend further back from the end of the line than the last fully accented vowel. However, that does occur in some final couplets of Shakespeare's *Sonnets*, as in (4):

(4) Then will I swear beauty herself is black,
And all they foul that thy complexion
lack. (132, 13–14)

And rhymes that don't involve the last stressed vowel also occur, as in (5), at least assuming the contemporary stress pattern on *mónument*, a point to which we return below:

(5) And thou in this shalt find thy monument,
When tyrants' crests and tombs of brass
are spent. (107, 13–14)

Even these few familiar examples show, then, that while certainly conveying a common understanding of rhyme, this definition excludes from its scope even choices the most canonical English poet has made to fulfill what is taken as a defining requirement of the most canonical (and eponymous) form of English poetry – that a Shakespearean sonnet end with two rhymed lines.

At the other end of the spectrum, the *American Heritage Dictionary, second college edition (AHD)* defines rhyme simply as "correspondence of terminal sounds of words or of lines of verse." This succeeds in encompassing all the couplets of (1)–(5) within its scope, as well as more exotic examples we will see below. But it does so partly by being vague: one might well wonder, for example, what exactly is meant by 'correspondence', or by 'terminal'.

These two definitions and their respective hazards represent the Scylla and Charybdis that any account of rhyme must navigate – exactly the same faced by accounts of other linguistic forms such as relative clauses or the intonational patterns of questions. The description must be broad enough to encompass the full range of structures having a plausible and significant claim to be instances of the form, and at the same time it must be narrow enough to exclude imaginable similar structures that in fact seem not to occur. In addition to the usual methodological controversies about how to achieve such a description, however, an added difficulty for rhyme is that in one of its central meanings at least – that which takes rhyme to be a characteristic of verse – it is not simply a naturally occurring form but rather a product of highly self-conscious, artful behavior designed to create specific expressive effects.

Nonetheless, approaching the description of rhyme as fundamentally a problem of linguistic form finds substantial justification. To begin with, we can observe that both definitions agree that rhyme is a relationship between linguistic entities of some kind; melodic figures passed from violins to viola to cello in a string quartet may have identical or corresponding structures, but they do not rhyme, except perhaps metaphorically. Any description of rhyme and its variant forms is thus inevitably at least partially a linguistic description. Still, the genuinely linguistic part of the description might be limited; a description of the crossword puzzle, for example, must necessarily be partially linguistic, depending on reference to linguistic entities like the word, but it must also involve other significant properties that have no role in language, such as whether a word is represented horizontally or vertically, or how many letters it is spelled with. As it happens, however, what research there has been so far into rhyme from an explicitly linguistic point of view suggests that the relationship to language is quite a fundamental one; systematically, growth in our understanding of language has yielded corollary insights into rhyme.

In fact, even before getting into any details of such descriptions, fundamental properties of language allow rhyme to be delimited further in important ways. First, the references to sound in both definitions suggest that the relationship is a phonological one. That distinguishes rhyme from at least one other closely related verse form that has sometimes been called rhyme, syntactic parallelism (Wimsatt, 1954). At the same time, it also allows rhyme to be recognized in sign languages, which have phonology that is not manifested in sound.

Furthermore, phonology itself is held to be organized along two quite distinct dimensions – *rhythm*, involving syllables, stress, phrasing, and so forth, and *melody*, the qualitative characteristics that define individual segments, such as the features that make an [s] different from a [z] or a [t] or an [n], or an [i] different from an [e] (Liberman and Prince, 1977; Goldsmith, 1979). Given this distinction, it seems clear that rhyme necessarily involves a relationship based on linguistic melody: *simple* and *border*, for example, have similar phonological structures in virtue of their rhythmic shapes, yet they do not rhyme in English; we will see below that this is not merely a prescription, even an intuitively acceptable one, but rather a description based on an empirical claim that poets do not seem to use such pairings to fulfill their rhyme schemes. While the family of verse forms based on rhythmic repetition has long been given the common name of poetic 'meter', rhyme clearly joins such forms as alliteration, assonance, and consonance in forming a family crucially based on melodic relationships. These are sometimes collectively called 'sound-patterning', but because it is not clear in what sense rhythm is not sound, except in the sense referred to earlier in which phonology in general is not sound, these forms might usefully be given an alternative common name such as poetic 'harmony' as proposed by Gostusky (1969), because they involve structured relationships among the component parts of linguistic melodies.

Both definitions also take rhyme to be a relationship between ends. It is this that distinguishes them from at least one of these other poetic harmonies, alliteration, which by definition relates melodies at beginnings, such as the [d]'s at the beginnings of the words *day, daily, draw* (and perhaps also *doth*) in (2) above.

Finally, we can assert without any argument beyond common experience, because it will be developed much more fully below, that the nature of the relationship, somewhere between the *COED*'s 'identity' and the *AHD's* 'correspondence', involves some kind of likeness – like all verse forms, rhyme is a form of repetition.

These considerations give, then, as a starting point, a somewhat revised version of the capacious definition given by the *AHD* of rhyme as minimally a relationship of likeness between final linguistic melodies. So far, however, this revision does little to address the vagueness of the original. In fact, we will see that the best way to do that seems to be not to define rhyme more narrowly, but rather to articulate the specific sources of the variation found in rhymes across languages and across individual poets' practices. In a useful article modestly purporting merely to bring some order to the chaos of overlapping terminology used for rhyme and other harmonic forms, Rickert (1978) identifies three distinct sources of variation: where the language involved in the relationship is located in a text, exactly which segments in those locations are constrained by the form, and exactly what degree of similarity those constraints require. The first two specifications, we will see, can jointly answer the question of what exactly is meant by 'final' in our definition, and the third will answer the question of what exactly constitutes a 'likeness', our compromise between 'identity' and 'correspondence'. Thus, the range of possible answers to these three questions can generate a typology of rhyme, and it is around them that the following discussion is organized.

What makes these questions of particular interest to linguists is the theoretical question to which we referred briefly earlier, the question of the extent to which the range of possible answers might itself be constrained by linguistics. For example, building on the perspective of Jakobson (1960), Kiparsky (1973, 1987) articulated a substantive hypothesis, already latent in much inquiry into rhyme, that the structures in terms of which poetic forms are defined are precisely those that also figure in grammar. In particular, he suggested that rhyme bears significant resemblances to reduplication. If this is correct, we would expect answers to our questions to make reference to linguistic entities such as word boundaries, syllable nuclei or back vowels, but not, for example, to 'important' words, or even, as is often assumed to be the case, to spelling. Of course, the issue is complicated by the fact that the hypothesis defines other poetic forms too, such as metrical feet and lines, which are likewise linguistic in the sense of being defined in reference to linguistic entities but are not part of ordinary language and to which descriptions of rhyme must plainly make reference. Perhaps more cautiously, then, we can say, especially in light of the artistry with which rhyme is created as noted above, that answers to our questions that refer to linguistic entities define rhymes that are natural, either directly, referring to structures of ordinary language, or indirectly, referring to specifically poetic forms that themselves are natural in this way; poets may

or may not also create rhymes that are defined in other ways and that are thus definably artificial. In any case, this interesting theoretical question is far from settled, nor is there even that much in the way of rigorous description of rhyme available against which to test it. On the contrary, even for such a well-documented poetic tradition as that of English, in many ways the study of rhyme is in its infancy, rich with open research questions.

Finally, a word is in order about the methodology that has shaped linguistic inquiry into rhyme. First, the question of what does or does not rhyme is essentially a question about an individual poet's competence in exactly the sense that term has within linguistics: knowledge that governs intuitions about well-formedness, whether conscious or unconscious, codified or not. That competence may also be complex in the same ways as other linguistic knowledge can be, encompassing differences according to genre and purpose or period of composition, just as speakers may control different registers, and their languages may include various dialects. Generalizations about rhyme must therefore always be understood as essentially claims about commonalities across individual competences.

Second, the best and usually only evidence for a poet's intuitions about rhyme is his or her actual practice. As Kiparsky (1973) noted, answering the question of what counts as a rhyme for a poet is really only possible to the extent that it is possible to identify a rhyme scheme – a pattern in which rhymes recur in some arrangement that is sufficiently predictable that it is possible to assert that two items that seem rather different nonetheless must rhyme in the poet's estimation because the scheme he or she has created calls for them to, and because there is no reason to think the scheme has simply been abandoned. For example, it is the claim that the Shakespearean sonnets discussed earlier share a rhyme scheme of 'ababcdcdefefgg' that motivates the insistence that rhyme must be defined for Shakespeare in such a way as to account for the fact that for him, all of the pairings in (1)–(5) are evidently rhymes. Kiparsky's term for this is that the rhyme is 'obligatory' as opposed to 'optional', the same distinction drawn between the more traditional terms 'structural' and 'ornamental'. It is always worth bearing in mind, however, that 'obligatory' is also relative to different languages, periods, and genres; as Fabb (2002) noted, the interpretation of a scheme as obligatory is essentially a pragmatic inference that a poet has in fact committed him or herself to producing a rhyme at a certain point, and as such it is both contextual and fallible in all kinds of ways. In fact, the questions of what rhyme schemes occur in poetry and how exactly we come to perceive them are thus fascinating and open in themselves, but also in many ways beyond the bounds of linguistics proper, even as assumptions about them underpin linguistic investigation.

In what follows, then, we return our attention to the narrower question of the form of rhyme and some recent attempts to offer precise descriptions of particular rhyme practices, clarifying their relationship to aspects of phonological structure and exploring parallel phenomena in grammar itself. The illustrations will be drawn mostly from English because the data from English can be presented with the most confidence, but it should be emphasized that key concepts are drawn from work on not only English but also Finnish, Irish, Turkish, Hebrew, French, German, Dutch, Romanian, and many other languages, as indicated in the bibliography.

The Location of Rhymes

We have said that rhyme is by definition final, a melodic likeness between ends; but our first question is, ends of what? As we will see, the question does not necessarily have a simple answer: the hierarchical organization of both linguistic rhythm and verse structure makes available a rich variety of constituents whose ends are in principle available for defining rhymes, and are in fact combined in various and sometimes complex ways by different poets.

In the canonical case of perfect rhyme illustrated in (1), the rhymes occur at the ends of metrical lines. By definition, a metrical line has a rhythmic structure just as all language does as part of its phonological structure that consists of its parse into such entities as syllables (σ), feet (ϕ), words (ω), phrases (Φ), etc., in what is inspiringly but somewhat confusingly called its 'metrical phonology' (*see* **Metrical Phonology**). But a line of metrical verse also has a (poetic) metrical structure, a parse that shows its phonological rhythmic structure to satisfy whatever additional constraints define the meter. The metrical parse is thus closely related to the phonological parse, but also in principle is distinct from it. One way of modeling meter that makes the distinction particularly vivid is through a metrical template that defines some abstract rhythmic structure together with a set of correspondence rules that define mappings of the rhythmic structure given by the phonology into that template (*see* **Meter**). For iambic pentameter, for example, the meter of the example in (1), the template has been argued to be that in (7), consisting of five rising feet, each composed of a weak position (W) followed by a strong one (S), with these feet grouped in turn ambiguously into two rising cola, which are grouped finally into a line:

(7)

The iambic pentameter of Shakespeare's *Sonnets* includes the constraint that there is one syllable in each position, and (8) shows the language of the lines in (1) mapped into the template in accordance with that constraint and others (such as a constraint that stressed syllables of polysyllabic words like *remembered* be mapped into strong metrical positions). The template is shown fully for this first example, but abbreviated thereafter; and the rhythmic structure of the language is likewise partially represented just this once to give the basic idea:

(8)

a. For thy sweet love rememb'red such wealth brings,

b. That then I scorn to change my state with kings,

W S W S W S W S W S

The interest of this for rhyme is that when language is mapped into the template in this way, and so defined as metrical, it is in a sense also defined as having two ends, each in its turn definable at a variety of levels: there is the end of the template – the final strong position, foot, colon, etc. – as well as the end of the language mapped into it – its final syllable (σ), foot (ϕ), word (ω), phonological phrase (Φ) etc.

In lines like those in (8), the end of the language coincides with the end of the template in what is called a 'masculine ending', whence the term 'masculine rhyme' for rhymes between lines of this type. It is therefore possible to locate the rhymes in either the final syllables of the lines, or the final strong positions of the lines, without particularly needing to attend to any potential distinction between the two. But this is by no means the case for all rhymes. Even for these simple masculine rhymes, note that once the role of meter in locating rhymes is properly articulated, it is no longer necessary or even correct for accounts of rhyme in verse to locate rhymes in terms of a last accented vowel, at least not for Shakespeare's *Sonnets*. Rhymes like that in (5) that rhyme a stressed syllable with an unstressed one in what is sometimes called a 'tangential rhyme' can be seen when scanned as in (9) to follow from exactly the same characterization as rhymes like those in (8) as located in the final syllables, which are those in the final strong positions:

(9) And thou in this shalt find thy monument,
w s w s w s w s w s
When tyrants' crests and tombs of brass are spent.
w s w s w s w s w s

In fact, it seems quite possibly generally true that stress does not matter to well-formedness in rhyme directly, but only indirectly through its contribution to meter – whence the confinement of rhyme to melodic likeness suggested earlier. Note that this predicts that vowel length, too, might well be generally irrelevant to well-formedness in rhyme. But at the same time, further research might well turn up a practice that exploits this distinction between metrical and rhythmic structure in genuinely locating rhymes in syllables containing last accented vowels, rhyming *spent* in (9) for example with *entity,* but not with *monument*.

Meters also allow non-coincidence of the end of the language of a line and the end of a template. In a metrical version of phonological extrametricality, for example, the iambic pentameter of Shakespeare's *Sonnets* allows an optional additional unstressed syllable ('<>') line-finally, as in the scansion of (2) in (10), traditionally called a 'feminine ending', and whence the term 'feminine rhyme' for a rhyme between two lines of this type:

(10) But day doth daily draw my sorrows longer,
w s w s w s w s w s <>
And night doth nightly make grief's length seem
w s w s w s w s w
stronger.
s <>

In the common case illustrated here, the location of the likeness that defines the rhyme begins in the syllable in the final strong position, as in the rhymes in (1), but continues through the end of the language of the line.

In English, it is most common for masculine lines to rhyme with masculine lines and feminine with feminine, but these are not the only possibilities. There are also what are called 'androgynous' rhymes in which the two line types are mixed. Shakespeare's *Sonnets* include at least one possible rhyme of this type, and his plays include other clear examples. In the 'b's' of the 'abab' quatrain in (11a), scanned in (11b), the syllable in the strong position of the feminine line does not figure in the rhyme: as it does not in the couplet in (12a), scanned in (12b).

(11a) For when these quicker elements are gone
In tender embassy of love to thee,
My life being made of four, with two alone
Sinks down to death, oppressed with
melancholy; (45: 6,8)

(11b) In tender embassy of love to thee,
w s w s w s w s w s
Sinks down to death, oppressed with melancholy;
w s w s w s w s w s <>

(12a) Quite overcanopied with luscious woodbine,
With sweet musk-roses and with eglantine
(A Midsummer Night's Dream [italicized]
2.2.251-2)

(12b) Quite overcanopied with luscious woodbine,
w s w s w s w s w s <>
With sweet much-roses and with eglantine
w s w s w s w s w s

Instead, the syllable that the final one of the masculine line is like is the extrametrical syllable in the feminine line. The meter thus defines what counts as the line, but the end of it that is relevant to rhyme is the end of the language mapped into the template and not the end of the template itself.

Conversely, in another type of androgynous rhyme sometimes called 'apocopated' (but perhaps overdue to be revised to something more like 'drag queen' rhyme so that the nameless adventurous structures in (12), those feminine lines behaving as if they were masculine, can be recognized as 'drag king' rhymes), it is the extrametrical syllable that does not figure in the rhyme. The likeness holds instead between the syllables in the final positions, regardless of what follows them. An example (for which I am indebted to Michael Ferguson) is the rhymes of the mixed iambic pentameter and tetrameter couplets of James Merrill's *The Octopus* as in (13), scanned in (14) (on the assumption that the iambic pentameter of this poem differs from Shakespeare's *Sonnets* in allowing two unstressed syllables in a single weak position, (*see* **Meter**):

(13) There are many monsters that a glassen surface
Restrains. And none more sinister

(14) *There are* many monsters that a glassen surface
w s w s w s w s w s <>
Restrains. And none more sinister
w s w s w s w s

Finally, these possibilities suggest that even when both lines are feminine, some poets might rhyme only the syllables in the final metrical positions, or only those that are final in the language, or mix the two.

Nor is extrametricality the only source of complexity in locating rhymes. The foregoing are examples of what is called 'end-rhyme', which in spite of rhyme being always an end phenomenon, is not redundant, because it refers specifically to the rhymes being located at ends of lines, when they might be at ends of other constituents. 'Internal rhyme', another special case noted by the *COED*, refers generally to rhymes in which at least one partner is not final in the line. Internal rhyme can be as systematic as end rhyme, and also as complex. One relatively straightforward example might be the rhyme between *sed* and *med* in the third line of the stanza of the Middle English *Cuckoo song* in (15), which can be characterized as a rhyme of the final syllable (or position) in the line with the final syllable (or position) in the first colon of the same line:

(15) Sumer is i-cumen in –
Lhude sing, cuccu!
Groweth sed and bloweth med
And springth the wude nu.
Sing, cuccu!

Medieval Irish included a variety of stanzaic forms defined by both end rhyme schemes and internal rhyme schemes, including systematic rhymes between the ends of certain lines and the ends of the first cola or even in some cases the first words of the succeeding lines, as in the rhymes of *amra* and *fagla*, or *elta* and *Cerca* in (16), examples from Murphy (1961) for which I am indebted to Eve Sweetser (and in which the nature of the likeness defining the rhymes will be discussed more fully below):

(16) Anmchaid Osraigi amra
cáini fagla flathrígi
drecon bruthmar bruithe elta
mac Con Cerca cathmíli.

Some of these internal rhymes, it should be noted, deepen the question of exactly what is a line. Why, for example, should a line like the third one in (15) be counted as one long line with internal rhyme rather than as two short ones with end rhyme? Should rhyme perhaps be seen as capable of creating lines, rather than simply marking ends of ones defined by meter? After all, meter is not the only way of defining a linguistic entity that has an end. Is rhyme ever based on the ends simply of phrases, or of sentences? In modern poems that define lines only visually through page-layout, do rhymes occur at ends whose definitions bypass considerations of language and meter entirely? The scope for complex relationships arising through rhyme from diverse ways of defining ends, while not without limits, is far greater than standard accounts of rhyme have tended to acknowledge. Poets have found these complexities, and linguists and critics are just beginning to catch up: Shoptaw (2004), for example, has recently argued that some

of Dickinson's poems involve 'counter-lineation', in which visual and metrical lines pointedly and significantly diverge, and interlocking rhyme patterns are defined over both.

And of course, internal rhymes are not necessarily systematic at all; in a quatrain like that in (17) from another of Shakespeare's *Sonnets*, the most that can be said of its abundant internal rhymes is that they are final in the words involved:

(17) *Will* will fulfill the treasure of thy love,
Aye, fill it full with wills, and my will one.
With things of great receipt with ease we prove,
Among a number one is reckoned none: (135, 5–8)

In sum, then, we can say that rhyme is indeed a relationship of likeness between ends, and that it is only possible to speak of a rhyme scheme if it is possible to specify which ends in some systematic way. At the same time, the rich range of constituents made available by language and meter – let alone by nonlinguistic structures such as page layout – provide a surprisingly complex and varied range of possible structures whose articulation and delimitation raise many interesting open questions for a theory of rhyme.

The Domains of Different Rhyme Types

The question of what is final involves not just where what is 'final' actually ends, but also where what is final starts – or put another way, over exactly what domain, measured how, likeness must hold in order to define a rhyme. Here again, there is a wide range of imaginable possible answers, and the specifically linguistic character of rhyme emerges in the extent to which the rhymes poets actually use are best characterized through reference either to linguistic constituents or to metrical constituents closely modeled on them.

In the example in (1) of a 'perfect' masculine rhyme, the language that is alike matches neatly the portion of the syllable actually called the 'rhyme' on analogy to the verse form. One fairly standard description of the internal structure of the syllable is that represented in (18), with the first segment in the nucleus being the most sonorous one, hence in most English syllables the first vowel. On this analysis, *brings* and *kings* would have the syllable structures in (18a,b), and hence identical syllable rhymes:

(18)

However, because in English at least, poets mix such rhymes quite freely with feminine ones, and in the latter the entire syllable succeeding the one in the strong position normally matches as well, as in (2, 10), this resemblance turns out to be rather less useful to a description of rhyme than might be expected. Rather, what the internal structure of the syllable seems to delimit is the beginning of the domain over which likeness holds (Holtman, 1996). The form of rhyme in which what is matched runs from the nucleus of some specified final syllable through its coda and on to some specified end, then, is the form known as 'full rhyme'. In many ways, taking both these monosyllabic masculine and polysyllabic feminine rhymes into account, what the domains resemble is the portion of a foot from its head on, with the metrical strong position defining that head; but given the complexity we have just seen regarding potential distinctions between metrical and rhythmic structure, the question of exactly what the domain of likeness is in polysyllabic rhymes clearly requires more research and careful formulation, especially involving traditions in which polysyllabic rhymes are the norm, such as Irish, as seen in (16) above.

Another significant form of rhyme involves less than the syllable rhyme, and that is 'slant rhyme'. In slant rhyme, syllable nuclei are irrelevant to well-formedness; only final consonants need bear any likeness to one another, as in the 'a' rhymes of *spoke* and *Lake* in the first 'aabb' stanza of Yeats's *Under Ben Bulben* in (19):

(19) Swear by what the sages spoke
Round the Mareotic Lake
That the Witch of Atlas knew
Spoke and set the cocks a-crow.

Here, too, there are interesting questions about how exactly to describe the form linguistically. First, it should be noted that it is only final consonants and not entire syllable codas that are alike in slant rhyme, at least in English; the form provides no evidence for the coda as a constituent. For example, in the stanza from Yeats's *Sailing to Byzantium* in (20), the 'abababcc' rhyme scheme is satisfied by the rhyme of *unless* and *dress* with *magnificence*:

(20) An aged man is but a paltry thing,
A tattered coat upon a stick, unless
Soul clap its hands and sing, and
louder sing
For every tatter in its mortal dress,
Nor is there singing school but studying
Monuments of its own magnificence;
And therefore I have sailed the seas
and come
To the holy city of Byzantium.

A second interesting question involves rhymes such as that of the second couplet in (19), in which no final consonants are present. In English, there seem to be two distinct traditions. One is represented by Yeats's practice, in which the vowels must be either both back, as in the rhyme of *knew* and *crow* in (19), or else both front as in, for example, the rhyme of *I* and *utterly* in *Easter 1916* (13–15). Since non-low tense vowels in English always end their articulation with glides sharing their features [± back], Yeats's rhyme seems to recognize the presence of final glides in apparently open syllables and to require that they be alike. In the other tradition, however, vowel-final rhymes observe no such constraint, as in, for example, Plath's rhyme of *go* and *lie* in the 'abcacb' scheme of *All the dead dears*:

(21) And to sanctuary: usurping the armchair
Between tick
And tack of the clock, until we go,
Each skulled-and-crossboned Gulliver
Riddled with ghosts, to lie
Deadlocked with them, taking root as cradles rock.

The latter case is, as observed by Kiparsky (1973), exactly parallel to the well-known pattern in Germanic alliteration, whereby initial consonants must match each other to satisfy the form, but initial vowels can match any other vowel; it is also in harmony with claims that no final glides are present in underlying representations of simple tense vowels (Chomksy and Halle, 1968). The simultaneous existence of the tradition represented by Yeats, however, suggests that there are open questions about the best way to model both practices and to represent the structures of the relevant syllables in English.

A final form of melodic repetition that is arguably a form of rhyme is 'assonance'. Assonance is the reverse of slant rhyme: in assonance, nuclei must bear a likeness to one another, but the consonants following them need not. One argument for treating assonance as a form of rhyme is that, although not as common as full rhyme or slant rhyme, it is used to instantiate schemes defined over line ends, as in some medieval French romances or in Dylan Thomas's *Fern Hill*, where assonances like *green* and *leaves* or *climb* and *eyes* and *light* instantiate an 'abcddabcd' scheme (Zwicky, 1976):

(22) Now as I was young and easy under the
apple boughs
About the lilting house and happy as the
grass was green,
The night above the dingle starry,
Time let me hail and climb,
Golden in the heyday of his eyes,
And honored among wagons I was prince
of the apple towns
And once below a time I lordly had the
trees and leaves
Trail with daisies and barley
Down the rivers of the windfall light. (1–9)

Here, the existence of phonological tiers that represent only vowels may be key to understanding assonance as a form of rhyme that can genuinely be said to be based on language that is final in some sense.

In sum, the domains over which the likenesses that define rhymes hold are not necessarily constituents. Conversely, certain linguistic constituents whose existence has been posited do not necessarily define rhyme types. At the same time, however, it seems that the demarcation of the domains of likeness is a matter of linguistic structure, either directly, or indirectly through metrical structure, insofar as their beginnings are the beginnings of well-defined constituents, rather like the domains posited by prosodic morphology (McCarthy and Prince, 1996).

It is also worth noting that it is sometimes suggested that rhymes are defined not just by required likeness, but also sometimes by required difference; the *COED*, for example, as mentioned earlier explicitly asserts that in English the likeness must not continue (moving back in the line) beyond the nucleus of the first syllable to include its onset, and some accounts of rhyme by linguists have attempted to model this constraint (Holtman, 1996; Yip, 1999). However, for English at least, this seems better understood as an evaluative prescription (possibly reflecting rejections of French rhyme in which such likenesses are actually highly valued) than as a systematic practice that a description of rhyme must account for; in (4) earlier, for example, we have already seen a counterexample, and Oras (1955) has argued that rhymes of just this type have been used in English throughout the tradition.

Partial Likenesses in Rhymes

Perhaps the richest question of all that rhyme poses for linguistics is that of what, exactly, counts as a sufficient likeness for a rhyme. It has long been recognized that in any of the earlier forms, sometimes the likeness that defines a rhyme involves mere similarity rather than complete identity. In one of the most influential articulations of the relevance of linguistics to the study of rhyme, Zwicky (1976) pioneered the explicit description of differences allowed in rhymes through reference to distinctive features, which was pursued further by Golston (1997) and others. Focusing on the rhymes of English rock lyrics,

Zwicky describes a form he calls 'rock rhyme', which is a full rhyme in the sense given earlier of requiring likeness from the nucleus in the final strong position, but which – alongside other special structures discussed further below – allows matched segments to differ by a single distinctive feature in any position. Thus in the 'abcbdefe' scheme of Bob Dylan's *Masters of war* in (23); in the first stanza, *desks* rhymes with *masks,* whose vowels [ɛ] and [æ] differ in the latter being [+low], while in the 'ababab' scheme of *Ballad of Hollis Brown*, in the third stanza in (24), *sleeve* rhymes with *breathe*, whose [v] and [ð] differ in the latter's not being [+labial]. And both the nuclei and the coda consonants differ (by [± back] and [± labial], respectively) in the rhyme of *guns/bombs* in (23):

(23) Come you masters of war
You that build all the guns
You that build the death planes
You that build the big bombs
You that hide behind desks
I just want you to know
I can see through your masks

(24) Your baby's eyes look crazy
They're a-tuggin' at your sleeve
Your baby's eyes look crazy
They're a-tuggin' at your sleeve
You walk the floor and wonder why
With every breath you breathe

Crucially, Zwicky argues that the rhyme of *sleeve* and *breathe* in (24) is not assonance, because across the whole song, the final consonants are not free as they are in genuine cases of that form, as in (22), but rather subject to the feature-based constraint on similarity he identifies. By the same reasoning, the rhyme of *desks* and *masks* in (23) is not slant rhyme, because across the song, the nuclei do not vary without limit – they vary only within the scope of the posited constraint. Put another way, full rhyme, slant rhyme, and assonance are defined just as discussed above by the different domains they impose constraints on – final nuclei and what follows, final consonants alone, or final nuclei alone, respectively – the question of whether those constraints require complete identity is in principle a separable one. If the constraints do not require complete identity, but do require some similarity that is statable in a systematic way, that becomes an argument for the inclusion of even differing segments within the domain of required likeness, and the rhyme may be termed 'partial'.

As Malone (1993, 1987) has pointed out, the general phenomenon Zwicky noted of the likenesses that define rhymes being satisfied by partial rather than complete identity is in fact not at all confined to rock lyrics but appears throughout the English tradition as well as in the rhyme traditions of other languages. When the practices of individual poets and traditions are considered separately, however, it is not as clear that Zwicky's definition of similarity as a single-feature difference is ever the best way to characterize the operative constraints. Rather, these seem to take a wide (though not limitless) variety of possible forms that submit to a wide (though not limitless) variety of explanations involving linguistic structure in a somewhat different way.

Perhaps the most familiar source of rhymes involving similarity rather than strict identity with a linguistic explanation is differences in pronunciation. An audience in one dialect may perceive only similarity where a poet composed a strict identity in another. For example, the assonance of *Fern Hill* in (22) is realized at one point by the pairing *barns/calves*, in which the vowels are different in many American dialects but not in Thomas's Welsh dialect. A particularly complex version of this question arises when describing the poet's dialect is itself a problem of historical reconstruction. For example, the question of whether Shakespeare's vowels are really different in quality in his rhymes of *prove/love* in (3) or even in stress in *monument/spent* in (5) is simultaneously a question about his rhyme practice and about his dialect, in that any reconstruction of his pronunciation must take into account the possibility that partial rather than complete identity may have sufficed for a rhyme, just as much as any account of his rhyme practice must take into account the possibility that these rhymes were strictly identical in his dialect (Kökeritz, 1953; Hanson, 2002). For it is clear that even partial rhymes that have their origins within the tradition in changed pronunciations cannot necessarily be claimed to have been complete at their moment of composition in the dialect of every poet who has used them; whatever their pronunciation in Shakespeare's dialect may have been, rhymes like *love/prove* persisted in being composed in English long after their vowels' qualities had undeniably diverged. It has sometimes been argued that such partial rhymes have continued to be used productively simply because the original usage has established them as conventional pairings, an approach commonly taken to both the many slight differences occurring, for example, in the vowels of English full rhymes and the differences in the consonants in Zwicky's rock rhymes, modeled as they often are on blues sung by musicians in whose dialects certain final consonants were deleted (Kiparsky, personal communication). But such accounts of historical origin do not preclude the possibility that the form in which they persist is not arbitrary pairings but grammatical generalizations (Hanson, 2002). In general, then, the influence

of dialect variation over both time and place remains an important open question in the study of virtually every poet's rhymes.

Another explanation for partiality in rhymes of linguistic interest involves the question of at what level of representation the relevant correspondence holds. An influential hypothesis put forth by Kiparsky (1968, 1972), that identities that appear only partial on the surface actually are complete in underlying representations, has been shown to explain rhyme patterns in a variety of languages (see, for example, Malone (1982, 1988) on Turkish or Malone (1983) on Hebrew). This hypothesis might even be illustrated for English by a simple case such as the rhyme of *monument/spent* in (5). Even if, as suggested earlier, the difference in the stress of their final syllables is irrelevant to the well-formedness of the rhyme, there remains the issue that, at least in contemporary pronunciation of these words, there is also a difference in the quality of their vowels, [ə] and [ɛ]. But when the final syllable of *monument* is stressed as in *mònuméntal*, the vowel that surfaces as ə in *monument* surfaces as ɛ instead; hence we may hypothesize that that vowel is ɛ underlyingly, and that that might therefore be the vowel figuring in the rhyme.

There is no question, however, that all partial likenesses in rhyme can be reanalyzed as complete in either of these ways. On the contrary, in some traditions, the partial likenesses that are allowed in rhyme are even codified. In Irish, for example, consonants are grouped into classes, any member of which can count as the same as the others for purposes of rhyme. One class, for example, is the 'k class' of the voiceless stops [p], [t], and [k] (spelled 'c'); and another is the 'l class' of voiced fricatives together with what are called 'weak sonorants', hence [v] (sometimes spelled 'b' or 'bh'), [ð] (sometimes spelled 'd' or 'dh', [γ] (sometimes spelled 'g' or 'gh'), [β] (sometimes spelled 'm' or 'mh') and [m], [n], [l] and [r]. In the internal rhymes mentioned in (16) earlier, then, which are polysyllabic rhymes, *amra* (a[βr]a) and *fagla* (fa[γl]a) rhyme because their medial consonants belong to the same succession of classes, as do those of *elta* (e[lt]a) and *Cerca* (ce[rk]a). A question of interest for the relationship of rhyme to linguistics is that of in what sense classes of this type are natural classes from a phonological point of view and what role they have in the language's ordinary grammar. In Irish, these classes used in rhyme do figure in the grammar, for example, as either targets or results of rules of lenition (Eve Sweetser, personal communication; Malone, 1987; Murphy, 1961.

And even without being codified in such a way, phonologically systematic partial rhymes emerge in other traditions. In English, for example, surprisingly many poets systematically allow consonants that differ in voice to nonetheless count as rhyming (Frawley, 1984). It is sporadic and historically debatable in some early texts, as in the particularly haunting rhyme of *glass/was* from Shakespeare's *Sonnets*:

(25) Then were not summer's distillation left
A liquid prisoner pent in walls of glass,
Beauty's effect with beauty were bereft,
Nor it nor no remembrance what it was. (5, 12)

But it is pervasive and undeniable in many other poets' practice, such as Pinsky's slant rhyme translation of Dante's *Inferno*, which regularly matches not only [s] with [z] but also [t] with [d], [f] with [v] and [ʃ] with [ʒ], as in his stanzas of "aba bcb cdc .." *terza rima* in (26) (Hanson, 2003):

(26) a. "A different path from this one would be best
For you to find your way from this feral place,"
He answered, seeing how I wept. "This beast,
The cause of your complaint, lets no one pass
Her way – but harries all to death. Her nature
Is so malign and vicious she cannot
appease (I 71–75)

b. It seemed it might never stop; behind it a train
Of souls so long that I would not have thought
Death had undone so many. When more than one
I recognized had passed, I beheld the shade
Of him who made the Great Refusal, impelled
By cowardice: so at once I understood (III 47–52)

c. Who set it there?" He said: "It should be clear:
Over these fetid waves, you can perceive
What is expected – if this atmosphere
Of marsh fumes doesn't hide it." Bow never drove
Arrow through air so quickly as then came
Skimming across the water in a little
skiff (VIII 11–16)

d. You will be brought to shore by another way."
My master spoke then, "Charon, do not rage:
Thus is it willed where everything may be
Simply if it is willed. Therefore, oblige,
And ask no more." That silenced the grizzled jaw
Of the gray ferryman of the livid marsh, (III 76–81)

Other common partial matches in English involve nasals that differ in place, as in Dylan's rhyme of *guns* and *bombs* in (23), or another of Pinsky's in (27):

(27) If it should please you, stop a moment here.
Your way of speaking shows that you
were born
In the same noble fatherland: there where
I possibly have wrought excessive harm."
This sound erupted from a coffer of stone –
I drew back toward my guide in my alarm. (X 22–27)

And as in Irish, these equivalences in rhyme invite phonological inquiry into why these particular partialities should be used. The discounting of voice in rhyme in English, for example, can be related to the neutralization of voice distinctions in codas in English that leads to alternations like that between [s] and [z]

in the plural (as in *cat*[s] but *dog*[z]) or [t] and [d] in the past (as in *bark*[t] but *meow*[d]) (Hanson, 2003). This, in turn, can be related to a more general diminution of the perceptibility of the voicing contrast in final position, as suggested by Steriade (forthcoming). Even in English, however, not all poets allow the same partially similar segments to count as alike in rhyme; Dickinson, for example, allows rhymes of obstruents that differ in place, a pairing not used by Pinsky that suggests that different poets partition the phonological space in different ways.

In sum, some partiality in what counts as a likeness is actually the rule rather than the norm in at least some poetic traditions, and, it should be emphasized, is available in all rhyme forms, for example, in full rhyme, just as much as in slant rhyme or assonance. Such partiality may have a variety of sources, but in all cases, the question of how the specific partialities poets use are related to linguistic structure seems a fruitful and worthy avenue of study on a poet-by-poet basis in a wide range of languages.

Subsequence

A final complexity in rhyme also noted by Zwicky for English rock rhymes, but seeming to have far wider applicability as well as significant linguistic interest, is 'subsequence'. On Zwicky's description, subsequence is the presence in one rhyme partner of a segment not matched in the other; an example again from *Masters of War* is the final [z] in *eyes* not present in its rhyme partner *fly* in the 'abcbdefe' scheme in (28), while the extra [t] in *fleet'st* compared to its partner *sweets* in (29) shows a similar structure in an 'abab' quatrain from Shakespeare's *Sonnets*:

(28) You that never done nothin'
But build to destroy
You play with my world
Like it's your little toy
You put a gun in my hand
And you hide from my eyes
And you turn and run farther
When the fast bullets fly

(29) Make glad and sorry seasons as thou fleet'st,
And do what e'er thou wilt, swift-footed Time,
To the wide world and all her fading sweets:
But I forbid thee one most heinous
crime: (19, 5–8)

Subsequence seems, however, to be somewhat more constrained than Zwicky's description allows, and in ways that point to interesting possible explanations for it in relation to syllable structure (Golston, 1997). Golston observed that in Dylan's rhymes, subsequent segments can be argued to be always final, and also always coronals. This seems to hold true for many other English poets as well; allowing a final extra [s] or [z] is widespread, with some poets also allowing an extra [t] or [d], and in some complex cases involving feminine endings, possibly even an extra [n]. Why should such structures count as rhymes? Golston related the phenomenon to observations by Borowsky (1986) and others that English syllable rhymes normally permit only three segmental positions (with long vowels counting as two), thus allowing for example *sneak* ([ɪnk]) or *ink* [iŋk] but not **sn*[iŋk]. Final coronals, however, are allowed in excess of this constraint, as in *fiend* ([ind]) or *fierce* ([irs]), suggesting that the final coronals may be external to the syllable rhyme, perhaps incorporated instead as an appendix as in (30):

(30)

Furthermore, among all the coronals, [s/z] has been argued to be peripheral to syllable structure on different grounds, including its being excepted from the universal constraints that the sonority of segments should decrease or at least remain level across a coda as in the [rs] of *fierce*, rather than increasing as it does in, for example, the [ks] of *sphinx* (Harris, 1994). The proper analysis of these linguistic phenomena is debated; but in any case it is clear that subsequence in rhyme provides an at least partially parallel phenomenon whose description and explanation awaits research.

Resemblances to Reduplication

We have up to this point considered rhyme as a verse form that both as a whole and in individual poets' practices seems to bear systematic relationships to the phonology of ordinary language. Nothing in the description of the phenomenon we have developed so far, however, confines rhyme to verse; in fact, neither does either dictionary definition with which we began, because both allowed for rhyme simply at 'ends of words'. It is, in fact, perfectly reasonable to speak even more generally of words whose syllables rhyme, whether in the manner of full rhyme as in *picnic* or *claptrap*, or slant rhyme in *riffraff*, or even of apocopated rhyme in, say, a phrase like *a very married pair.*

The relationship of rhyme to ordinary phonology that has probably been of the most interest to linguists, however, is not sporadic rhymes, whether

intentional or not, or even the influence of rhyme on vocabulary development; but rather the fully systematic grammatical process of reduplication. Kiparsky's suggestion, with which we began, that the linguistic structures that figure in verse are fundamentally the same ones that figure in grammars, offered parallels with reduplication as its evidence (specifically, parallels between alliteration in Germanic verse and Gothic past tense formation). A few linguists have developed the parallel in fruitful and extensive ways, including Holtman (1996), Yip (1999), and, with reference specifically to language acquisition, Inkelas (2003). It seems quite likely that understanding such issues as the polysyllabic rhythmic structures onto which melodies are copied in reduplication, or melodic simplifications implemented in copying, will illuminate answers to the basic question of why poets count what they do as rhymes.

Conclusion

The interest of rhyme for linguistics may be a matter of its form alone, but the consequences of description and explanation of its forms reach beyond linguistics into literary criticism and theory. In the interpretation of poetry, one of the most vexing questions is that of the nature of the contribution forms make to meaning, or more generally to aesthetic effect – not just the legitimacy of arguments from one to the other, but even the legitimacy of positing the existence of such forms to start with, especially in the face of the evident variation they exhibit. While linguistic investigation of rhyme by no means settles these philosophical questions, attention to it expands enormously our awareness of the range of phonology that seems available to give rise to aesthetic effects, both in modulation across obligatory rhyme schemes (Lanz, 1931) and in relationships forged by optimal ones (Wimsatt, 1954). The project should thus be of interest to literary critics and linguists alike.

Rhythm

T Riad, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Definition

Rhythm is the perception of a pattern of alternation between prominent and nonprominent prosodic elements. In a linguistic context, rhythm is mostly discussed in the domains of stress patterns and verse metrics. Rhythm is deeply involved in the shape of stress systems, stress being probably the only phonological category that has a rhythmic distribution (Hayes, 1995: 25). The rhythmic character of stress distribution is evident, for example, in six-syllable words, in which stress will tend to occur on every other syllable (σσσσσσ or σσσσσσ). No language will assign stress to three adjacent syllables in such a word (*σσσσσσ or σσσσσσ). Furthermore, it is natural to view the categories of linguistic stress (the binary prosodic feet) and their distribution in words as part of the linguistic manifestation of rhythmic structure. In spoken language, rhythm also comes up in conjunction with rhythmic adjustments of different kinds (destressing, stress shift, addition of stress). The pattern of regular alternation is thought of as prototypically rhythmic, but the notion of rhythm is more inclusive than that in linguistics, especially when we extend the focus to verse metrics. In meter, less symmetric patterns, such as those found in the verse of Sappho, would also qualify as rhythmic, provided they occur with some regularity. Thus, rhythm could be defined as an arrangement of prominent and nonprominent prosodic elements that can be perceived as a regular pattern.

Rhythmic structure is hierarchical and it has been represented both as tree structure and grid structure in the phonological literature. In the following grid structure, hierarchy is coded as different heights of the columns, reflecting level of prominence. This would be a typical rhythm of a song or nursery rhyme (example from Hayes (1995: 26)).

```

Definition

Rhythm is the perception of a pattern of alternation between prominent and nonprominent prosodic elements. In a linguistic context, rhythm is mostly discussed in the domains of stress patterns and verse metrics. Rhythm is deeply involved in the shape of stress systems, stress being probably the only phonological category that has a rhythmic distribution (Hayes, 1995: 25). The rhythmic character of stress distribution is evident, for example, in six-syllable words, in which stress will tend to occur on every other syllable (σσσσσσ or σσσσσσ). No language will assign stress to three adjacent syllables in such a word (*σσσσσσ or σσσσσσ). Furthermore, it is natural to view the categories of linguistic stress (the binary prosodic feet) and their distribution in words as part of the linguistic manifestation of rhythmic structure. In spoken language, rhythm also comes up in conjunction with rhythmic adjustments of different kinds (destressing, stress shift, addition of stress). The pattern of regular alternation is thought of as prototypically rhythmic, but the notion of rhythm is more inclusive than that in linguistics, especially when we extend the focus to verse metrics. In meter, less symmetric patterns, such as those found in the verse of Sappho, would also qualify as rhythmic, provided they occur with some regularity. Thus, rhythm could be defined as an arrangement of prominent and nonprominent prosodic elements that can be perceived as a regular pattern.

Rhythmic structure is hierarchical and it has been represented both as tree structure and grid structure in the phonological literature. In the following grid structure, hierarchy is coded as different heights of the columns, reflecting level of prominence. This would be a typical rhythm of a song or nursery rhyme (example from Hayes (1995: 26)).

```
(1) x                                                   x
    x                   x                               x                   x
    x       x           x           x                   x       x           x       x
    x   x   x       x   x       x   x       x           x   x   x       x   x   x   x   x
    This        old         man                         he          played          one,
    he          played      knick-      knack           on          my              thumb,      with    a
    knick-      knack       pad-    dy  wack,           give    your    dog     a   bone,
    this        old         man         came            rol-            ling            home.
```

Rhythmic structure strives toward even spacing at all intervals of repetition. Thus, feet tend to yield alternating rhythm, as in Example (2). Phrasal stresses, too, tend to be evenly spaced, even though the number of unstressed syllables vary (see later, Example (9)). If the distance becomes too long, new, rhythmically motivated stresses will occur. Rhythmic structure also exhibits synchronization of beats at all levels, as in Example (1) (downward implication). Thus, a syllable receiving phrasal stress will also carry a word stress and will be the head of a foot. Representationally, this means that high grid marks are always on the top of a column. These properties are all testable through ordinary experience, i.e., 'tapping' in response to rhythm and sensing what is natural and what is not.

Eurhythm

Alternating rhythm is unmarked, and unmarked rhythm is optimal in language. Optimal rhythm, or eurhythm, is to some extent attained by virtue of the canonical shapes of linguistic feet as iambic (. x) or trochaic (x .). Sequences of iambs or trochees will inevitably instantiate alternating rhythm:

(2) Iambic:	(. x)	(. x)	(. x)	(. x)
	σ σ	σ σ	σ σ	σ σ
Trochaic:	(x .)	(x .)	(x .)	(x .)
	σ σ	σ σ	σ σ	σ σ

Eurhythm is attained also by adjustment processes of various kinds. There are two prototypical nonrhythmic contexts (so-called arrhythmies) to which languages typically show a reaction: clash and lapse. Clash is the situation whereby two prominences are adjacent at some level. The specification of what counts as a clash and a lapse may vary according to language (Nespor and Vogel, 1989). The typical reaction to clash is the reduction of the lesser stress, as in the following cases from Swedish:

(3) 'kvar-ˌskatt → 'kvar-skatt
'residual tax'
tull-ˌpack-ˌhus-ˌkarl-s-ˌlag→
'tull-pack-ˌhus-karl-s-ˌlag
'customs packing house men's team'

In the second example, the resulting rhythm ('*tull-pack-ˌhus-karl-s-ˌlag*) is regularly alternating, by virtue of every other stress being retained. Lapse – the situation when the distance between stresses is too great – is resolved by the insertion of a rhythmic prominence somewhere between the stresses, as in the following example from Italian (Nespor and Vogel, 1989: 86):

(4) Giánni non ce lo dá → Giánni non cè lo dá
'Gianni does not give it to us.'

Resolution of clash and lapse involves the deletion and addition of stress beats. In principle, the combination of those two processes will also describe the process of stress shift. So-called iambic reversal (the rhythm rule, stress retraction) of English is one example of this:

(5) thìrtéen mén → thìrteen mén

Clash resolution by stress shift respects the hierarchical level at which stress clash occurs. This can be brought out in a grid representation (Prince, 1983):

(6)
```
        x                   x                 *          x
  ←   (x)   x         (x)   x             (x)    x
x     x     x         x     x     x       x     x     x
x   x x x   x         x   x x x   x       x   x x x   x
achromatic lens  →  achromatic lens     achromatic lens
```

As seen, the stress shifts to the next prominence on its own level, rather than just to the next syllable, which would create an ill-formed grid structure. Example (6) also illustrates the fact that rhythmic adjustment need not be triggered by a clash in the narrowest sense, since in this example, an unstressed syllable comes between the clashing ones.

The picture that emerges is one in which the linguistic feet encode the basic rhythmic property of alternation, and linguistic rules adjust the distribution of stress in connected speech. The upshot is an approximation of equally spaced prominences. However, the feet and the adjustment rules are not enough to achieve even spacing.

Rhythm in the Speaker and Listener

Rhythm does not arise simply as a function of the sheer distribution of phonological prominences in a linguistic structure. It also arises by virtue of the execution of the prosody of a linguistic structure, wherein the distribution of stresses can be made more even by the regulation of speech tempo. Furthermore, the interpretation of auditory impressions goes some way toward creating rhythm. The tendency to adjust the distance between stresses is typical of languages such as Swedish or English, and it is supremely clear in verse metrics:

(7) x . x . x . . x
Humpty Dumpty sat on a wall

x . x . x . . x
Humpty Dumpty had a great fall

(8) x . . x . . x . . x . . x . . x .
Sjung, o guidinna om vreden som brann hos peliden Akilles
'Sing, O goddess, the anger of Achilles son of Peleus'

x . x . . x . . x . . x . . x .
Olycksdiger till tusende kval för akajernas söner
'that brought countless ills upon the Achaeans.'

In each of these verse samples, a nursery rhyme and the first two lines of the Iliad in a Swedish translation, the stresses are equally spaced, despite the fact that the number of unstressed syllables between them varies.

We find the same phenomenon in spoken language, but here the isochrony is more approximate. In the following example, taken from Engstrand (2004: 205) there are four stress groups, containing radically different numbers of syllables:

```
(9)  .    x . .  .    .    x  .  .    x    .    x
     σ |  σ σ σ  σ    σ |  σ  σ  σ |  σ    σ |  σ
     Och | tjejerna kom och | skrek att det | brann som | fan
     'And the-girls came and shouted that it burnt like hell.'
```

In the actual pronunciation of this utterance, the groups are of roughly equal length, which means that the syllables of the first group are pronounced much faster than are those of the third and fourth. Regulations in speech tempo also affect the very application of rhythmic adjustment rules. Indeed, in slow and careful speech, adjacent stresses might not induce the sense of clash, and in fast speech, some syllables may be suppressed altogether.

The degree of isochrony varies depending on structural properties of the language, such as phonotactics, quantity system, and gradation (Strangert, 1985). Indeed, there is a traditional notion that languages could be categorized as syllable timed or stress timed (e.g., Abercrombie, 1967), the idea being that some languages would strive toward equal distance between syllable peaks (Italian, Spanish), whereas other languages would strive toward equal distance between stresses (German, English). In an influential paper, Dauer (1983) showed that rhythm in the languages in her sample were all stress based, acoustically, and that they come differently close to isochrony. In fact, the evidence for acoustically even spacing is quite weak. Perceptually, however, things are different. Perception may give a rather strong sense of isochrony even when the physical correlate is quite uneven, and it might also allow for the impression of syllable timing. The findings of Dauer show that it is possible to retain stress as the single phonological unit in language that has a rhythmic distribution. Syllables do not form the base for rhythm, and neither do other linguistic categories. Also, it is clear that phonological rules pertaining to stress apply so as to create even, rather than uneven, rhythm, as we have seen.

Grouping: Iambic/Trochaic Law

Beside its role in the rhythm of spoken language, perception is also crucially implicated in the derivation of linguistic feet – that is, grouping, from basic input to rhythm. The empirical finding among stress systems in languages is that iambic systems tend to have long syllables in the prominent position of the foot, whereas trochaic systems tend to have short syllables in the same position. Stated differently, there seems to be a bias to have uneven quantity in the two positions of an iamb, but even quantity in the positions of a trochee. There is a perceptual base for this, known in phonology as the iambic/trochaic law, which builds on the insights of psychological experiments on rhythmic grouping (see Hayes, 1995: 79, and references therein):

```
(10) – ´ – ´ – ´ – ´ –      →  – (´ –) (´ –) (´ –) (´ –)
     – — – — – — – — –      →  (– —) (– —) (– —) (– —) –
```

If the input varies in intensity, people will tend to group the inputs in units with initial prominence, viz., trochees. If the input varies in quantity, the inputs will be grouped as iambs, with final prominence. Beyond foot structure, there are phonological rules of lengthening and shortening in iambic and trochaic systems, respectively, that work in the direction of optimizing the pattern in accordance with Example (10) (see Mester, 1994).

Meter

In spoken language, rhythmic properties are essentially automatic. In poetic meter, prosodic properties of the language become codified. Unmarked properties may be enhanced, as in the isochrony of the nursery rhymes shown in Examples (1) and (7). However, in many styles of verse, it is considered crude to overstate the rhythmic pattern in the manner done in nursery rhymes, and rhythm is instead signaled more subtly. One exponent for this in the English tradition is blank verse, in which none of the metrical positions actually requires of the syllable filling it that it be either stressed or unstressed. Similarly, meter can be consciously made to deviate from the unmarked. Indeed, any verse tradition containing more than one meter must have less marked meters in it. Classical Greek meter is traditionally considered a quantitative system, based on long and short syllables, but it explores arrhythmic properties such as clash and lapse in the construction of meter. Thus, for dactylic meter, the essential rhythmic property is one clash per metron, and for iambic meter it is one lapse per metron. Interestingly, clash and lapse are not very strong constraints in the language, and it would seem that this is what makes it possible to explore these arrhythmies in the verse tradition (Golston and Riad, 2000). For languages without stress, e.g., Japanese, we expect that they should have very little in the way of rhythmic phenomena in both language and verse. The verse types used in Japanese (haiku, tanka), which count moras but exhibit no sensitivity

to prominence, certainly seem to support this conclusion (Kozasa, 2000).

Rhythmic Alternations

D Zec, Cornell University, Ithaca, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Rhythmic alternation is a principle of linguistic organization that operates at the level of sound structure and is rooted in the cognitive organization of auditory events. As an organizing cognitive principle, rhythmic alternation grants cohesion to temporal spans, by virtue of propelling the regularity of event sequencing from past to future. This general cohesive role also characterizes rhythmic alternation in linguistic constituencies. Rhythm has a specific organization in terms of beat structure, detected in language as well as in other cognitive domains that are crucially dependent on the time dimension. According to studies of the rhythmic structures in music (Cooper and Meyer, 1960; Lerdahl and Jackendoff, 1983), as well as investigations of linguistic rhythm (Liberman, 1975; Liberman and Prince, 1977; Hayes, 1995), auditory stimuli are construed as beats, and a sequence of beats is further construed as a sequence of groups of beats with recurring group internal structure. In its turn, group internal structure is manifested as greater prominence conferred on one of the group members, typically the first or last, thus yielding an alternating pattern.

Studies of the cognitive properties of rhythm have reported on the general conditions for the emergence of rhythmic alternation (Fraisse, 1978; Woodrow, 1951). According to Woodrow (1951: 1232), "[b]y rhythm, in the psychological sense, is meant the perception of a series of stimuli as a series of groups of stimuli. The successive groups are ordinarily of similar pattern and experienced as repetitive." Trochaic grouping tends to be perceived when the sequence consists of equidistant auditory events alternating in loudness, whereas iambic grouping emerges when alternating sounds are longer in duration, or are followed by a longer pause. The optimal temporal interval for rhythmic grouping is relatively small, to facilitate the perception of a group as a whole, that is, as a single perceptual event. These findings about the general cognitive properties of rhythm elucidate the nature of rhythmic patterning in language.

The Scope of Rhythmic Alternation in Language

Rhythmic alternation in linguistic constituents is most directly evidenced in alternating stress patterns. Phonological theories have captured the basic aspects of rhythm by representing both grouping and prominence (Halle and Vergnaud, 1987; Halle and Idsardi, 1995; Hayes, 1995; Prince, 1990). Thus, in Example (1), each syllable of *Mìssissíppi*, which has an alternating stress pattern, corresponds to a beat (line (a)), with the first and third beats more prominent than the second and fourth (line (b)), and the third beat more prominent than the first (line (c)). Beats are represented by the symbol x, groups are identified by parentheses, and degrees of prominence are captured by the height of the beat column.

```
(1) (c)     (           x     )
    (b)     (x          x     )
    (a)     (x    x)    (x    x)
            M ì s s i   s s í p p i
```

However, rhythmic alternation in language is constrained in several ways. Whereas domains such as

to prominence, certainly seem to support this conclusion (Kozasa, 2000).

Rhythmic Alternations

D Zec, Cornell University, Ithaca, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Rhythmic alternation is a principle of linguistic organization that operates at the level of sound structure and is rooted in the cognitive organization of auditory events. As an organizing cognitive principle, rhythmic alternation grants cohesion to temporal spans, by virtue of propelling the regularity of event sequencing from past to future. This general cohesive role also characterizes rhythmic alternation in linguistic constituencies. Rhythm has a specific organization in terms of beat structure, detected in language as well as in other cognitive domains that are crucially dependent on the time dimension. According to studies of the rhythmic structures in music (Cooper and Meyer, 1960; Lerdahl and Jackendoff, 1983), as well as investigations of linguistic rhythm (Liberman, 1975; Liberman and Prince, 1977; Hayes, 1995), auditory stimuli are construed as beats, and a sequence of beats is further construed as a sequence of groups of beats with recurring group internal structure. In its turn, group internal structure is manifested as greater prominence conferred on one of the group members, typically the first or last, thus yielding an alternating pattern.

Studies of the cognitive properties of rhythm have reported on the general conditions for the emergence of rhythmic alternation (Fraisse, 1978; Woodrow, 1951). According to Woodrow (1951: 1232), "[b]y rhythm, in the psychological sense, is meant the perception of a series of stimuli as a series of groups of stimuli. The successive groups are ordinarily of similar pattern and experienced as repetitive." Trochaic grouping tends to be perceived when the sequence consists of equidistant auditory events alternating in loudness, whereas iambic grouping emerges when alternating sounds are longer in duration, or are followed by a longer pause. The optimal temporal interval for rhythmic grouping is relatively small, to facilitate the perception of a group as a whole, that is, as a single perceptual event. These findings about the general cognitive properties of rhythm elucidate the nature of rhythmic patterning in language.

The Scope of Rhythmic Alternation in Language

Rhythmic alternation in linguistic constituents is most directly evidenced in alternating stress patterns. Phonological theories have captured the basic aspects of rhythm by representing both grouping and prominence (Halle and Vergnaud, 1987; Halle and Idsardi, 1995; Hayes, 1995; Prince, 1990). Thus, in Example (1), each syllable of *Mìssissíppi*, which has an alternating stress pattern, corresponds to a beat (line (a)), with the first and third beats more prominent than the second and fourth (line (b)), and the third beat more prominent than the first (line (c)). Beats are represented by the symbol x, groups are identified by parentheses, and degrees of prominence are captured by the height of the beat column.

```
(1) (c)     (           x     )
    (b)     (x          x     )
    (a)     (x    x)    (x    x)
            M ì s s i   s s í p p i
```

However, rhythmic alternation in language is constrained in several ways. Whereas domains such as

music demonstrate a cognitive capacity for groupings at multiple hierarchical levels of rhythmic structure (Lerdahl and Jackendoff, 1983), rhythmic constituency in language is fairly shallow. Hierarchical rhythmic organization in language is highly restricted and mainly follows from the hierarchical organization of the linguistic constituents that serve as potential domains for rhythmic patterning. Likewise, whereas the cognitive capacity for manipulating groups with more than two members, and with more elaborate internal organization, is evidenced in domains other than language (Fraisse, 1978), rhythmic patterns in language tend toward simple, binary groupings, as in Example (1). In fact, precisely because such alternating patterns are relatively simple, they can equally well be represented by the so-called grid structure, which lacks explicit grouping (Prince, 1983; Hayes, 1984, 1995; Selkirk, 1984; Gordon, 2002), as illustrated in Example (2). Representations in Examples (1) and (2) have identical prominence structures yet differ in how the regular alternation of prominent beats is formally executed. In Example (2), an alternating pattern is secured by invoking principles such as eurhythmy, a requirement for an even distribution of stresses, which should be neither too close to each other nor too far apart. That is, neither adjacent stressed syllables, or clashes, nor adjacent unstressed syllables, or lapses, are permitted:

```
(2) (c)                x
    (b)      x         x
    (a)      x    x    x    x
           M ì  s s i  s s í  p p i
```

Ternary groupings, while rare, have also been evidenced among alternating stress patterns. In these systems, stressed syllables alternate with intervals of two unstressed syllables. Phonological analyses either admit ternary groupings into the set of possible group types (Halle and Vergnaud, 1987; Levin, 1988), or posit binary groups separated by an additional unstressed syllable (Hayes, 1995), or posit grid structures with a special license for lapses (that is, adjacent unstressed syllables) (Elenbaas and Kager, 1999; Gordon, 2002).

Patterns of Rhythmic Alternation in Word Phonology

Rhythmic alternation belongs to the range of possible phonological patterns for expressing prominence relations within words. Rhythmic alternation is most directly manifested in stress systems, which provide an abundance of relevant cases and set the scope within which this organizational principle is manifested in human language. However, rather than being a general property of word stress, rhythmic alternation characterizes only those stress systems that permit more than one stress within the word domain. Moreover, alternating patterns are not restricted to stress, and are encountered in other word prominence systems as well. Groupings in either stress or non-stress alternating patterns are subject to the same principles, rooted in the cognitive aspects of rhythmic alternation.

Alternating Patterns of Stress

Crucial in the classification of stress systems is the prosodic unit that serves as the basic rhythmic beat. Units that naturally emerge in this role are the mora and the syllable, both members of the prosodic hierarchy (Hayes, 1981, 1995; Halle and Vergnaud, 1987; Kager, 1995; and the references cited in these works). The syllable is the optimal candidate, due to its stable internal constituency and the high sonority of its nucleus. There are, however, two independent issues relevant for beat selection: which unit serves as a phonetically realized beat, and which serves as a beat for the purposes of computing an alternating pattern. Empirical evidence points at the syllable as the phonetically realized beat, but stress in general, and its alternating patterns in particular, can be computed with either the mora or the syllable taken as the basic beat. The two classes of stress systems, syllabic and moraic, are further subclassified into those with trochaic (left-dominant) or iambic (right-dominant) grouping. This yields four types of stress systems. Three of those, syllabic trochees, moraic trochees, and moraic iambs, are amply exemplified in Hayes (1995) and Kager (1995). Syllabic iambs present a special case and are addressed here.

Regular rhythmic alternation is most readily exhibited in systems of syllabic trochees. An alternating pattern can be computed either from left to right, as in Example (3), or from right to left, as in Example (4). Stressed syllables are marked as ó, with no distinction between primary and secondary stress, since both degrees of stress are equally relevant for rhythmic alternation.

Syllabic trochees: left-to-right:

```
(3) (ó o)
    (ó o) (ó)
    (ó o) (ó  o)
    (ó o) (ó  o) (ó)
    (ó o) (ó  o) (ó  o)
```

Syllabic trochees: right-to-left:

```
(4)  (ó o)
      o (ó o)
     (ó o) (ó o)
      o (ó o) (ó o)
     (ó o) (ó o) (ó o)
```

In Example (3), based on languages such as Icelandic, Hungarian, or Maranungku (Hayes, 1995), rhythmic alternation proceeds from left to right. Note that in words with an odd number of syllables, the final group is not binary, but for this very reason, stress alternation is regular. Systems minimally departing from Example (3) (e.g., Pintupi; Hayes, 1995) lack stress on the final syllable. As a result, words with an odd number of syllables have adjacent weak beats, as in (ó o) o and (ó o) (ó o) o, with a disruption of the alternating pattern at the right edge. In Example (4), based on languages such as Warao or Cavineña (Hayes, 1995), rhythmic alternation proceeds from right to left. Systems minimally departing from Example (4) are those in which word-initial syllables attract stress, yielding adjacent weak beats in words with an odd number of syllables, as in (ó o) o (ó o). This is the so-called initial dactyl effect (described in Prince (1983), Cohn (1993), and Hayes (1995), among others).

Alternation in stress systems that take the mora as the basic beat is of a less robust nature. In this case, the alternating pattern is computed over moras, yet stress is realized on syllables. Crucially, regular alternation at the level of moraic groupings need not be realized as regular alternation at the level of syllables. Groupings into moraic trochees include two light syllables ($ó_L$ o_L), or one heavy syllable ($ó_H$). However, whereas forms with all light syllables will exhibit perfect stress alternation, forms that combine light and heavy syllables may not, as in ($ó_H$) ($ó_L$ o_L) ($ó_H$), wherein stresses on the first two syllables clash (e.g., Fijian; Hayes, 1995). Likewise, groupings into moraic iambs include two light syllables ($ó_L$ o_L), one heavy syllable ($ó_H$), or a light followed by a heavy (o_L $ó_H$). In this case, again, a stress clash may arise at the level of the syllables, as in ($ò_H$) ($ò_L$ o_L) ($ó_H$), even though alternation at the level of the mora is perfectly regular (e.g., Asheninca; Hayes, 1995).

The Trochaic/Iambic Law

Alternating patterns are well attested for three out of four grouping types – for all, that is, other than the system of syllabic iambs. Only a single case of what appear to be syllabic iambs (Weri) is listed in Hayes (1981). Hayes (1995) eliminated syllabic iambs from the set of possible groupings, thus introducing an asymmetry into the system and motivating it by the general cognitive properties of rhythmic alternation. According to Woodrow (1951: 1233), "with equal temporal spacing, a regularly recurring, relatively greater intensity exerts a group-beginning effect, and a regularly recurring, relatively greater duration a group-ending effect." In other words, alternation in intensity produces trochaic grouping, and alternation in duration produces iambic grouping. These asymmetric grouping tendencies are evidenced in music (Cooper and Meyer, 1960: 10) and, according to Hayes (1995: 79–82) and Prince (1990), are also evidenced in rhythmic patterns in language.

Groupings in the two moraic systems exhibit a crucial asymmetry of the predicted sort: trochaic groupings, ($ó_L$ o_L), ($ó_H$), are even, and iambic groupings, (o_L $ó_L$), ($ó_H$), (o_L $ó_H$), may be uneven (Hayes, 1995; Kager, 1995; Prince, 1990). There is no (o_H o_L) trochaic grouping; in fact, systems of moraic trochees exhibit so-called trochaic shortening, as in Fijian (Hayes, 1995), reinforcing the strong preference for even trochees. Moreover, (o_L o_H) appears to be the preferred iamb, as evidenced by numerous cases of iambic lengthening, the effect of which is to eliminate feet of the (o_L $ó_L$) shape and reaffirm the preference for uneven iambs (Hayes, 1995). However, in the syllabic systems, all syllables are treated as equals, and as a result, all groups are even. Because of the preference for uneven iambic groupings, syllabic systems are inconsistent with iambic grouping. The strong theoretical position is that syllabic iambs are either highly disfavored (Prince, 1990) or are eliminated from the system (Hayes, 1995). It should be noted, however, that Gordon's (2002: 522) broad survey of syllabic stress systems included eight cases of syllabic iambic groupings, thus strengthening the empirical basis for positing this type of stress alternation.

Other Alternating Patterns in Word Phonology

Though most directly, and predominantly, manifested in stress systems, rhythmic alternation is not entirely restricted to them. Equally relevant, though not as well attested, are rhythmic alternations in phenomena other than stress, such as vowel length or vowel quality, which ultimately belong to the phonological devices for expressing degrees of prominence. Interestingly, clear cases of this type are characterized by moraic groupings. Three such cases are presented here. The Creek language exhibits covert rhythmic alternation: the place of tonal accent is computed by virtue of left-to-right iambic grouping, yet only the rightmost iambic group is phonologically marked by tone (Hayes, 1995). Next, Chickasaw exhibits rhythmic lengthening that in no obvious way relates to stress, and affects every second light syllable computed from left to right (Munro and Willmond, 1994; Hayes, 1995). Finally, Old Church Slavonic has an alternating pattern defined by Havlík's law, exhibited by high lax vowels (Isačenko, 1970). When two open syllables, both containing high lax vowels, are adjacent, the first one is lowered to a mid-vowel. Moreover, grouping proceeds from right to left: in words with only high lax vowels, lowering takes effect in every

even-numbered syllable from the end. In sum, cases of rhythmic alternation unrelated to stress provide strong evidence for full integration of rhythmic alternation into the inventory of possible phonological patterns.

Rhythmic Alternation in Phrasal Domains

Though the domain of rhythmic alternation is word-sized for only a subset of languages characterized by stress, any language with word stress could potentially exhibit rhythmic distribution of stresses within phrasal domains. Moreover, though rhythmic alternation at the word level is subject to a tight phonological organization, inter-stress intervals in the phrasal domain are under looser phonological control. This is in part because regular distribution of stress in phrasal domains crucially depends on word size. However, though there is no evidence for clearly defined groupings comparable to those at the word level, phonological regularizations of phrasal rhythm do occur, as in the well-studied case of the 'rhythm rule' in English (Liberman and Prince, 1977; Hayes, 1984, 1995; Selkirk, 1984; Kager and Visch, 1988; and references therein). As illustrated in Example (5), stress in *thirtéen* shifts leftward when followed by a stronger stress, resulting in an alternating rhythmic pattern. Rhythmic alternation is represented here with grids, first introduced by Liberman and Prince (1977) to accommodate this type of rhythmic adjustment:

```
(5)          x          x
       x     x     x    x
     x x     x     x x  x
  thirteen men→thirteen men
```

Crucially, stress shifts leftward only if there is an appropriate landing site: stress will only shift onto a syllable with secondary prominence. However, rhythmic adjustments of this type are not mandatory, but, rather, point at a strong tendency toward eurhythmy – that is, toward rhythmic alternation – in phrasal domains. Comparable rhythmic effects have been observed in German (Kiparsky, 1966) and Dutch (Kager and Visch, 1988), as well as in Polish, Italian, and Greek (Nespor and Vogel, 1989) (for additional cases, see Hayes (1995)).

The Phonetic Realization of Rhythm

In studies of speech rhythm, a well-known proposal is the division of languages into two rhythmic types: stress timed and syllable timed (Pike, 1945; Abercrombie, 1967). In the former type, stressed syllables occur at equal time intervals, and in the latter type, all syllables occur in such fashion. Thus, the former type is characterized by stress-based isochrony, and the latter by syllable-based isochrony. Note that the assumed isochronous intervals provide a basis for an alternating rhythm only in stress-timed languages.

Phonetic studies have refuted this sharp division. Dauer (1983) failed to identify differences in the duration of inter-stress intervals between Spanish, classified as a syllable-timed language, and English, a stress-timed language. Moreover, Wenk and Wioland (1982) demonstrated that French, presumably a syllable-timed language, is not characterized by an increase of word duration proportional to the number of syllables. However, though there is no clear case for isochrony at the level of production, it has been found that there is a strong tendency toward isochrony at the perceptual level: inter-stress intervals tend to be perceived as more isochronous than what would be expected from their actual durations (Lehiste, 1977; Scott and Isard, 1985). A further important finding is that perception of the isochrony of inter-stress intervals is stronger within, than across, linguistic constituents (Donovan and Darwin, 1979). In sum, phonetic studies of rhythm have identified inter-stress intervals as intervals that tend to be perceived as such, though not necessarily recurring with relatively stable durations. Yet, this rhythmic alternation is evidenced only in a fairly weak sense.

Riau Indonesian

D Gil, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

Riau Indonesian is the variety of colloquial Indonesian spoken by the inhabitants of the Indonesian province of Riau, which encompasses parts of east-central Sumatra plus a large number of adjacent smaller islands. Riau Indonesian is one of many distinct local varieties of colloquial Indonesian spoken throughout the archipelago, such as, for example, Jakarta Indonesian. The population of Riau province, numbering close to 5 million people, is linguistically and ethnically heterogeneous. Although the indigenous population is mostly Malay, a majority of the present-day inhabitants are migrants from other provinces, speaking a variety of other languages. Riau Indonesian is acquired as a native language by most or all children growing up in Riau province, whatever their ethnicity. It is the language most commonly used as a lingua franca for interethnic communication, and, in addition, it is gradually replacing other languages and dialects as a vehicle for intraethnic communication.

Riau Indonesian is quite different from Standard Indonesian, a language familiar to many general linguists from a substantial descriptive and theoretical literature. Riau Indonesian is also distinct from a set of dialects generally referred to as Riau Malay, used in Riau province by ethnic Malays, primarily for intraethnic communication. In addition, Riau Indonesian is distinguished from another set of Malayic dialects spoken by various indigenous peoples in Riau province (Orang Asli, Orang Sakai, Orang Akit, Orang Hutan, and Orang Laut). Finally, Riau Indonesian is also different from the variety of Malay/Indonesian sometimes referred to as 'Bazaar Malay,' which is used by the ethnic Chinese residents of Riau province when speaking to non-Chinese, and by the non-Chinese when speaking to the ethnic Chinese. Thus, the sociolinguistic situation in Riau province is one of great complexity: speakers of Riau Indonesian are often fluent in several other varieties of Malay/Indonesian, as well as in other languages, such as Minangkabau and Javanese.

From a general typological perspective, Riau Indonesian is a strongly isolating language, with no inflectional morphology and relatively little derivational morphology or compounding. It is also a

Riau Indonesian is the variety of colloquial Indonesian spoken by the inhabitants of the Indonesian province of Riau, which encompasses parts of east-central Sumatra plus a large number of adjacent smaller islands. Riau Indonesian is one of many distinct local varieties of colloquial Indonesian spoken throughout the archipelago, such as, for example, Jakarta Indonesian. The population of Riau province, numbering close to 5 million people, is linguistically and ethnically heterogeneous. Although the indigenous population is mostly Malay, a majority of the present-day inhabitants are migrants from other provinces, speaking a variety of other languages. Riau Indonesian is acquired as a native language by most or all children growing up in Riau province, whatever their ethnicity. It is the language most commonly used as a lingua franca for interethnic communication, and, in addition, it is gradually replacing other languages and dialects as a vehicle for intraethnic communication.

Riau Indonesian is quite different from Standard Indonesian, a language familiar to many general linguists from a substantial descriptive and theoretical literature. Riau Indonesian is also distinct from a set of dialects generally referred to as Riau Malay, used in Riau province by ethnic Malays, primarily for intraethnic communication. In addition, Riau Indonesian is distinguished from another set of Malayic dialects spoken by various indigenous peoples in Riau province (Orang Asli, Orang Sakai, Orang Akit, Orang Hutan, and Orang Laut). Finally, Riau Indonesian is also different from the variety of Malay/Indonesian sometimes referred to as 'Bazaar Malay,' which is used by the ethnic Chinese residents of Riau province when speaking to non-Chinese, and by the non-Chinese when speaking to the ethnic Chinese. Thus, the sociolinguistic situation in Riau province is one of great complexity: speakers of Riau Indonesian are often fluent in several other varieties of Malay/Indonesian, as well as in other languages, such as Minangkabau and Javanese.

From a general typological perspective, Riau Indonesian is a strongly isolating language, with no inflectional morphology and relatively little derivational morphology or compounding. It is also a

language with very flexible word order. Perhaps the most striking feature of Riau Indonesian is the pervasiveness of underspecification, i.e., the absence of obligatory overt grammatical expression for a wide variety of semantic categories, including number, definiteness, tense, aspect, thematic role, and ontological type. On the basis of these characteristics, Riau Indonesian has been argued to have a simple grammar, lacking much of the machinery central to most grammatical theories. Syntactically, it is said to have a single open syntactic category, that is to say, no distinction between nouns, verbs, adjectives, and prepositions, or between lexical categories and phrasal ones. Semantically, it is claimed that when two or more expressions are combined, the meaning of the combination is usually associated with the meanings of the constituents in a vague and underspecified fashion.

Richards, Ivor Armstrong (1893–1979)

N Kerecuk, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Ivor Armstrong Richards, a British literary theorist, critic, poet and educator, was born in Cheshire, United Kingdom, in 1893. He was educated at Clifton College in Bristol. Originally, he read history but changed to moral sciences at Magdalene College graduating in 1915. After recovering from tuberculosis, he decided to study medicine but was invited to teach at the new English School (faculty) at Magdalene College in 1919, where he stayed until 1939. He traveled and taught throughout the world, especially in China and Japan. In 1944, he became a professor in the Department of Education at Harvard University, where he taught until 1963. He maintained his contacts with Magdalene College and returned to Cambridge in 1974. He died in Cambridge in 1979.

In 1918, he met Charles Kay Ogden (1889–1952), beginning a cooperation in philosophical linguistics. In 1957, Ogden wrote about the circumstances in which they met and how they discussed some of the controversies that were debated in *Mind* and particularly on how quickly Richards and Ogden produced an outline for *The meaning of meaning*.

In 1922, *The foundations of aesthetics* was published by Richards, Ogden, and James Wood (painter). In this work, there is a discussion of beauty that was treated more comprehensively in *The meaning of meaning*: it contains 16 senses of the word 'beauty' examined psychologistically. Ogden was a student of and was influenced by the heritage of the thoughts of Lady Victoria Welby (Gregory) (1837–1912), an independent scholar. In the late 19th century, she published papers on meaning, 'significs', in *Mind* and *The Monist*. Lady Welby started the 'signific movement' especially through the *Signifische Kring* in The Netherlands in 1917, when she met the Dutch poet and psychotherapist Frederik van Eeden (1860–1932), and she would later announce a Welby prize for original ideas on meaning that led to the development of Basic English. She was also active in the Vienna Circle and, of necessity, was influenced by the ideas that migrated to Vienna. Lady Welby also corresponded with C. S. Peirce (1839–1914). Lady Welby's thoughts influenced both Richards and Ogden.

In 1923, Ogden and Richards published *The meaning of meaning. A study of the influence of language upon thought and of the science of symbolism*. This work made the authors very famous. For example, Bertrand Russell and Edward Sapir discussed and adopted this book as standard university reading text. In this work, they investigated the role that words play on thought, the symbolic and emotional functions of meaning, and they sought to improve the incipient behaviorism. Their semiotic triangle – thought or reference, symbol, and referent – has been disseminated among the various language sciences. The manner by which they described the relation between symbol and referent has been criticized within the discussions of theory of meaning. One of the perceived failures is that their model fails to account for the cognitive component of human communication. Richards also argued that human thought is metaphoric in this work.

Ivor Armstrong Richards, a British literary theorist, critic, poet and educator, was born in Cheshire, United Kingdom, in 1893. He was educated at Clifton College in Bristol. Originally, he read history but changed to moral sciences at Magdalene College graduating in 1915. After recovering from tuberculosis, he decided to study medicine but was invited to teach at the new English School (faculty) at Magdalene College in 1919, where he stayed until 1939. He traveled and taught throughout the world, especially in China and Japan. In 1944, he became a professor in the Department of Education at Harvard University, where he taught until 1963. He maintained his contacts with Magdalene College and returned to Cambridge in 1974. He died in Cambridge in 1979.

In 1918, he met Charles Kay Ogden (1889–1952), beginning a cooperation in philosophical linguistics. In 1957, Ogden wrote about the circumstances in which they met and how they discussed some of the controversies that were debated in *Mind* and particularly on how quickly Richards and Ogden produced an outline for *The meaning of meaning*.

In 1922, *The foundations of aesthetics* was published by Richards, Ogden, and James Wood (painter). In this work, there is a discussion of beauty that was treated more comprehensively in *The meaning of meaning*: it contains 16 senses of the word 'beauty' examined psychologistically. Ogden was a student of and was influenced by the heritage of the thoughts of Lady Victoria Welby (Gregory) (1837–1912), an independent scholar. In the late 19th century, she published papers on meaning, 'significs', in *Mind* and *The Monist*. Lady Welby started the 'signific movement' especially through the *Signifische Kring* in The Netherlands in 1917, when she met the Dutch poet and psychotherapist Frederik van Eeden (1860–1932), and she would later announce a Welby prize for original ideas on meaning that led to the development of Basic English. She was also active in the Vienna Circle and, of necessity, was influenced by the ideas that migrated to Vienna. Lady Welby also corresponded with C. S. Peirce (1839–1914). Lady Welby's thoughts influenced both Richards and Ogden.

In 1923, Ogden and Richards published *The meaning of meaning. A study of the influence of language upon thought and of the science of symbolism*. This work made the authors very famous. For example, Bertrand Russell and Edward Sapir discussed and adopted this book as standard university reading text. In this work, they investigated the role that words play on thought, the symbolic and emotional functions of meaning, and they sought to improve the incipient behaviorism. Their semiotic triangle – thought or reference, symbol, and referent – has been disseminated among the various language sciences. The manner by which they described the relation between symbol and referent has been criticized within the discussions of theory of meaning. One of the perceived failures is that their model fails to account for the cognitive component of human communication. Richards also argued that human thought is metaphoric in this work.

Richards regarded himself as a philosopher with interests in psychology, and his earliest papers were on aesthetics published in *Athenaeum* in 1919: 'Art and science,' 'Emotion and art,' 'Four fermented aesthetics,' and 'The instruments of criticism: expression.' At Magdalene College, he lectured on literary criticism (novel) and theory of criticism. He developed courses on practical criticism using his method of 'close reading' and courses on Samuel T. Coleridge, rhetorical theory, and British moralists.

He stated that poetry, which often stood for literature or art in his arguments, was central to everything, and soon he became a theorist of the arts. He was very interested in the effect that reading had on the minds of readers: He argued that each literary work read modified the person who read it. In 1925, he published *Principles of literary criticism*, which he had started writing in 1923. In this work, he aimed to place the arts at 'the forefront of all values' because he regarded arts as "the supreme mode of communication," as he wrote in a letter to D. E. Pilley (November 19, 1923). He intended to demonstrate the value of poetry within the context of the contemporary psychological framework. The norms and practices of science hindered the ability of man to read and write poetry, according to Richards, who aimed to reinstate poetic expression or discourse. In his 1926 *Science and poetry* (revised in 1935), he introduced 'pseudo-statements' (misinterpreted then as 'false statements') as poetic utterances that do not need to be judged for truth conditions as does a scientific statement. Because he was interested in improving the reading skills of the university students, he dedicated much effort to this end, which resulted in the publication of *Philosophy of rhetoric* in 1936 and *Interpretation in teaching* in 1938. He stated that he rejected Aristotelian and other traditional rhetoricians' thought and argued that rhetoric should be "a philosophical inquiry into how words work in discourse." He applied these principles to Mencius, the Chinese philosopher, while he was traveling in China. He learned some Chinese, developed a simplified form of literal translations, and his study was published in 1932 as *Mencius on the mind: experiments in multiple definition*.

Richards moved away from literary discussion after publishing *Practical criticism* and turned to educational theory and language teaching. By 1931, he returned to the ideas of a system of simplified language, Basic English, with Ogden. This led him to produce a list of 850 words with which almost all communicative needs can be expressed. He dedicated the rest of his life to this enterprise. He promoted world literacy. In his cooperation with Christine M. Gibson, he pioneered the use of audiovisual media resources to the teaching of English as a foreign language. His works represent an important chapter in the history of language teaching methodology in general and specifically in English.

Richter, Elise (1865–1942)

C Neis, Potsdam University, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Elise Richter was born March 2, 1865 in Vienna and died June 21, 1943 in Theresienstadt (now Terezín, Czech Republic). Richter was one of the leading figures of Romance philology and phonetics in the 20th century. Having enjoyed the benefits of private education, she was the first woman in Austria who passed the *matura* and one of the first three women who were allowed to study at the University of Vienna. Richter was the first female student at the department of Romance philology, where she studied with Adolf Mussafia (1835–1905) and Wilhelm Meyer-Lübke (1861–1936). She was awarded a doctorate in 1901. Her dissertation *Zur Entwicklung der romanischen Wortstellung aus der lateinischen* (1903) was inspired by Meyer-Lübke's *Grammatik der romanischen Sprachen* (1890–1902). It was also Meyer-Lübke who encouraged Richter to apply for a *Privatdozentur*. In 1903 she presented her habilitation *Ab im Romanischen* to the Philosophical Faculty at Vienna. Richter tried to demonstrate that the Latin preposition *ab* is still present in several prepositions in Romance languages (Italian: *da*, French: *à*, Spanish: *a* etc.). In 1907, the Ministry confirmed the *venia legendi* and appointed Richter as the first female *Privatdozent* in Austria and Germany. Being a woman, she never became *ordinaria*, but due to her generally acknowledged competence she became *extraordinaria* in 1921. As a result of the annexation of Austria by Germany in 1938, Richter was forced to resign because of her Jewish origin. In 1939, the International Federation of University Women offered some financial support to Elise and her sister Helene, had they agreed to immigrate to England. But Elise Richter refused to leave her home country ("*Alte Bäume verpflanzt man nicht*"). In 1942, she was deported to the concentration camp Theresienstadt, where she died on June 21, 1943.

At an early stage in her writings, Richter developed an independent method of research and exceeded her mentor Meyer-Lübke in originality. Her article *Die Rolle der Semantik in der historischen Grammatik* (1909) showed her independent manner of thinking as she applied the Neogrammarians' achievements (especially the *analogy*) to the field of semantics, which until that time had been considered as a domain separate from grammar. Richter's research was particularly focused on the historical development of Romance languages. In *Der innere Zusammenhang in der Entwicklung der romanischen Sprachen* (1911), Richter explained the development of Romance languages from Latin as a result of a change in word-order. In her attempt to incorporate psychological aspects into her research on syntax and semantics, she adopted the conceptions of Wilhelm Wundt and Karl Vossler, but she never succumbed entirely to Vossler's idealism.

Richter also made important contributions to phonetics (a domain included in her teaching duties), particularly to experimental phonetics. Stimulated by her Vienna colleague Trubetzkoy, Richter became a pioneer of phonology in Romance languages.

In many of her writings, Richter embedded her research within a larger context, including general linguistics, German linguistics, Romance literature, etc. Most of Elise Richter's innovative work has had a remarkable influence on the subsequent development of linguistics.

Rickford, John R. (b. 1949)

B McElhinny, University of Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Dr. John Rickford is Martin Luther King Jr. Centennial Professor of Linguistics and director of African and Afro–American Studies at Stanford University. He was born in Georgetown, Guyana, and has degrees from the University of California Santa Cruz (B.A., 1971) and the University of Pennsylvania (M.A., 1973; Ph.D. 1979). His work focuses on the history and current use of Caribbean Creoles and of African–American Vernacular English (AAVE), with particular emphasis on the development of variationist sociolinguistic methods, debates about the creolist and anglicist roots of AAVE, and the educational implications of linguistic analysis (the latter often in conjunction with his wife, Dr. Angela Rickford). Other important contributions have included the call for new approaches to class analysis in sociolinguistics, studies of ethnicity as a sociolinguistic barrier, sociolinguistic analyses of style, and articles about the ethical obligations of social scientists. He has published 10 books and over 70 articles, some of the most influential of which are listed in the following bibliography.

In 1996, after the Oakland school board's widely and heatedly discussed decision to recognize the vernacular of African–American students in an Ebonics instruction program, Dr. Rickford engaged in countless public discussions with academics, teachers, churches, professional associations, and journalists on the ways that widespread knowledge of the structure and history of AAVE can improve the success of African–American students in the language arts. This work was recognized by the Linguistic Society of America with its Linguistics, Language, and the Public award, and by the American Anthropology Association with its Anthropology in Media award. *Spoken soul: the story of black English* (2000), a book written with his son, journalist Russell John Rickford, demonstrates his flair for offering an accessible introduction to AAVE, and also includes an insightful overview of the debates around the Oakland school board decision. It is the 2002 winner of an American Book Award. A talented and award-winning teacher, John Rickford is known for exciting the interest and developing the skills of undergraduate and graduate students by creating numerous opportunities for them to engage in original, collaborative research, and for devoting generous amounts of time to mentoring junior scholars.

Right Node Raising

K Hartmann, Humboldt-Universitätzu Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

The term 'right node raising' refers to a coordination construction in which the right end of the first conjunct (i.e., the 'target') is not expressed, creating an information gap. The gap is resolved at the end of the last conjunct, where the missing part of the first conjunct is expressed overtly, as shown in Example (1). Here and in all subsequent examples, the target appears in square brackets; the information gap in the first conjunct is indicated by an underline (_):

(1) Sarah baked _, and Louise devoured [five pancakes].

Right node raising (RNR), a term due to Postal (1974), describes an analysis that assumes the target, which must be phonetically and grammatically identical in both conjuncts, to raise 'across the board' (ATB) to a right-adjoined position above the coordination. Raising is indicated by coindexed traces (*t*) in the base position (**Figure 1**). This analysis of RNR, which is found in Postal (1974, 1998), Williams (1990), Larson (1990), and Sabbagh (2003), among others, is referred to here as the 'raising analysis.'

An alternative analysis of RNR dispenses with literal raising of the target and assumes that the target is syntactically present in its base position in both conjuncts, but is phonetically empty in the first one (**Figure 2**, the 'phonetic analysis'; see Wexler and Culicover (1980), Wilder (1997), and Hartmann (2000)).

A third possibility to analyze RNR is to allow the target to be multiply dominated by two nodes at the same time. In this view (**Figure 3**), the target occupies several syntactic positions but is pronounced only in the rightmost position of the clause; this is the analysis of McCawley (1982, 1988), Blevins (1990), and Steedman (1985).

There has been a long-standing debate in the linguistic literature as to which of the three analyses is the most appropriate one. In the following discussions, some of the arguments that have been brought up to strengthen the phonetic analysis, in preference to the raising analysis, are given. This presentation does not intend to reproduce all aspects of the still ongoing debate; rather, it merely aims to give an impression of the kinds of constructions and arguments to be considered when investigating RNR.

Right Node Raising

K Hartmann, Humboldt-Universitätzu Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

The term 'right node raising' refers to a coordination construction in which the right end of the first conjunct (i.e., the 'target') is not expressed, creating an information gap. The gap is resolved at the end of the last conjunct, where the missing part of the first conjunct is expressed overtly, as shown in Example (1). Here and in all subsequent examples, the target appears in square brackets; the information gap in the first conjunct is indicated by an underline (_):

(1) Sarah baked _, and Louise devoured [five pancakes].

Right node raising (RNR), a term due to Postal (1974), describes an analysis that assumes the target, which must be phonetically and grammatically identical in both conjuncts, to raise 'across the board' (ATB) to a right-adjoined position above the coordination. Raising is indicated by coindexed traces (t) in the base position (Figure 1). This analysis of RNR, which is found in Postal (1974, 1998), Williams (1990), Larson (1990), and Sabbagh (2003), among others, is referred to here as the 'raising analysis.'

An alternative analysis of RNR dispenses with literal raising of the target and assumes that the target is syntactically present in its base position in both conjuncts, but is phonetically empty in the first one (Figure 2, the 'phonetic analysis'; see Wexler and Culicover (1980), Wilder (1997), and Hartmann (2000)).

A third possibility to analyze RNR is to allow the target to be multiply dominated by two nodes at the same time. In this view (Figure 3), the target occupies several syntactic positions but is pronounced only in the rightmost position of the clause; this is the analysis of McCawley (1982, 1988), Blevins (1990), and Steedman (1985).

There has been a long-standing debate in the linguistic literature as to which of the three analyses is the most appropriate one. In the following discussions, some of the arguments that have been brought up to strengthen the phonetic analysis, in preference to the raising analysis, are given. This presentation does not intend to reproduce all aspects of the still ongoing debate; rather, it merely aims to give an impression of the kinds of constructions and arguments to be considered when investigating RNR.

Figure 1 The raising analysis.

Figure 2 The phonetic analysis.

Considered in turn are the constituency of the target, the absence of locality restrictions in RNR, the interpretation of the alleged traces, and the scope effects between elements of the target and the remnant conjuncts.

The first argument in favor of the phonetic analysis and against the raising analysis concerns constituency. Movement (including rightward movement) is generally restricted to one syntactic constituent. The target in RNR, however, can either contain several constituents, i.e., a noun phrase (NP) and a prepositional phrase (PP), as in Example (2a) (Abbott, 1976), or it can be a nonconstituent, e.g., as the head of a noun phrase (Example (2b)). This deviation from regular movement has led several researchers to the assumption that RNR cannot be raising (e.g., see Gleitman, 1965; Abbott, 1976; Williams, 1978; van Oirsouw, 1983, 1987).

(2a) Smith loaned _, and his widow later donated [a valuable collection of manuscripts to the library].
(2b) Louise likes yellow _, but Sarah prefers pink [shirts].

The following German examples also show clearly that RNR does not respect constituency. In German, prepositions may not stay behind if the complement of the preposition is displaced. This holds for leftward movement of the complement (Example (3a)), as well as for rightward movement (Example (3b)). Example (3b) illustrates heavy-NP-shift of a noun phrase originating in the complement position of the preposition *über* 'about'. The ungrammaticality of both examples indicates that German disallows preposition stranding. As shown in Example (3c), heavy-NP-shift is possible if no preposition is stranded in the midfield (*t*, trace of movement; DAT, dative):

(3a) *[$_{NP}$Dem Tisch]$_1$ sitzt Louise [$_{PP}$auf t_1].
the.DAT table sits Louise on
(3b) *Auf dem Empfang wurden wir [$_{PP}$über t_1] informiert [$_{NP}$das sehr reichhaltige Angebot an erlesenen Speisen und Getränken]$_1$.
at the reception were we about informed the very varied collection of selected dishes and drinks
(3c) Auf dem Empfang wurde uns t_1 serviert [$_{NP}$ ein sehr reichhaltiges Angebot an erlesenen Speisen und Getränken]$_1$.
at the reception was us.DAT served a very varied collection of selected dishes and drinks
'At the reception, we were served a very varied collection of selected dishes and drinks.'

Figure 3 The multidominance analysis.

As Example (4) shows, a preposition may strand in German RNR (Hartmann, 2000: 58), and the same holds for Irish (see McCloskey, 1986). This fact strongly suggests that RNR does not involve rightward ATB movement of the target:

(4) Louise sitzt auf _, und Sarah sitzt unter [dem Tisch].
Louise sits on and Sarah sits under the table
'Louise is sitting on, and Sarah is sitting under the table'.

The second argument corroborating the phonetic analysis shows that RNR does not obey well-known locality restrictions. It has been shown that targets may be contained within syntactic islands. Wexler and Culicover (1980), Goodall (1987), and Phillips (1996) argued that RNR freely violates the *wh*-constraint: in Example (5a) (Wexler and Culicover, 1980: 299), the target is contained in a *wh*-clause, which usually represents an island for movement. Neijt (1979: 44) claimed that the target may be part of a complex NP (Example (5b)), known to disallow extraction of constituents contained therein. Thus, RNR does not seem to be restricted by typical locality constraints:

(5a) Mary knows a man [$_S$who buys _], and Bill knows a man who sells [pictures of Fred].
(5b) Alfonse discussed [$_{NP}$the question of which rice _], and Mary discussed the question of which beans [we would eat].

The references compare RNR only with leftward movement, but since movement to the right considerably differs from movement to the left, the comparison must include RNR and clear instances of rightward movement, in order to make the argument valid. It can be argued that extraposition (= movement to the right) may not violate the coordinate structure constraint. In Example (6a), the PP *to the swimming pool* is extraposed out of the first conjunct of a coordinated verb phrase (VP), resulting in an ungrammatical sentence. In RNR (Example (6b)), on the other hand, the coordinate structure constraint

does not seem to be violated: although the PP *to school* originates in a coordinated VP, it can function as an RNR target. This would be unexpected if RNR were an instance of rightward ATB movement:

(6a) *Louise [$_{VP}$[$_{VP}$goes t_1] and [$_{VP}$reads a book]] [$_{PP}$to the swimming pool]$_1$.
(6b) Louise [$_{VP}$[$_{VP}$had coffee] and [$_{VP}$walked _]], but Sarah overslept and ran [to school].

The third argument is semantic in nature. It concerns the interpretation of traces. If RNR did involve movement, the traces of the alleged raising operation would be expected to be referentially identical. In other words, the target should refer to one and the same referent in both conjuncts. As Example (7b) shows, this expectation is not borne out (the argument is made for German in Klein (1993)):

(7a) What$_1$ did Louise buy t_1 and Sarah read t_1?
(7b) Louise bought _, and Sarah read [a novel].

In Example (7a), the *wh*-object is moved across the board to the sentence-initial position. The unique interpretation is that Louise and Sarah bought and read the same item. This reading is not predominant in the RNR sentence (Example (7b)), in which the novel bought by Louise and the novel read by Sarah may differ. Referential identity of the target is clearly excluded in Example (8); here, six goals were scored altogether, not three (unless they played against each other, of course!):

(8) Real Madrid scored _, and Bayern München got [three goals].

Since ATB movement obviously triggers referential identity of the moved constituents in both conjuncts, RNR in Examples (7b) and (8) cannot be derived by ATB movement, as assumed by the raising analysis. The phonetic analysis, on the other hand, captures the facts correctly.

The final argument presented here concerns scope effects. The raising analysis wrongly predicts that the target should be outside the scope of any element contained in the remnant conjuncts. However, the target appears not to have moved when variable binding, negative polarity licensing, and binding theory are considered (see Levine, 1985; Phillips, 1996; Hartmann, 2000). Phillips (1996: 53) argued that a quantifier may bind a pronoun contained in a target. This is possible only if the target is not attached higher in the tree than the quantifier is, given that the quantifier must take scope over the pronoun in order to bind it. As indicated by the indices, a bound reading of the pronoun is possible:

(9) Everyone$_1$ liked _, and at least one person$_1$ loved [the paper he$_1$ had been asked to review].

It is known that negative polarity items must appear in the scope of some negative element. According to the raising analysis, a negative polarity item in a target should be excluded, since the raised target is outside of the scope of the coordinated structure. This expectation is not borne out, as illustrated by Example (10) (Phillips, 1996: 53):

(10) Nobody enjoyed _, and few people even liked [any of the talks on RNR].

Finally, Levine (1985: 496) pointed out that the ungrammaticality of Example (11) cannot be explained if the target raises to some right-peripheral position, thereby bleeding the illicit binding of the referential expression *Mary* (contained in the target) by the pronoun *she*. The phonetic analysis offers a natural account for the ungrammaticality of Example (11), assuming that the target does not move:

(11) *I know that she$_1$ said _ and I happen to agree [that Mary$_1$ needs a new car].

To summarize, the aforementioned arguments all corroborate the phonetic analysis, which assumes that the target does not move, as first noted by Wexler and Culicover (1980). As has been indicated herein, these arguments represent only some aspects of an interesting and still open debate.

Rigid Designation

S Predelli, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Rigidity is a semantic notion. Semantics studies the relationships between expressions in a language and (typically) extralinguistic items. Examples of semantically interesting features are the relationship between the name 'George Bush' and Bush, the individual to which it refers; the relationship between the sentence 'George Bush is a liberal' and falsehood, its truth value; and, at least in some views, the relationship between the definite description 'the President of the United States' and Bush, the individual it denotes.

The task of a semantic theory is not that of immediately assigning the aforementioned features to the appropriate expressions. For instance, that the sentence 'George Bush is a liberal' is to be assigned falsehood depends not only on the semantic traits of the expressions under analysis, but also on obviously extrasemantic facts having to do with Bush's political convictions. By the same token, that the *denotatum* of 'the President of the United States' is George Bush, rather than John Kerry or myself, also depends on extrasemantic facts having to do with the results of the latest presidential election. For this reason, the aim of a semantic theory is that of presenting *relativized* assignments of semantic features. For instance, what our theory may conclude is that 'George Bush is a liberal' is true with respect to all and only those parameters that provide a positive reply to the query about Bush's leftist tendencies, and that 'the President of the United States' denotes Bush with respect to all and only those parameters with respect to which Bush won the presidential elections. According to a customary approach, parameters of this type may be understood as possible worlds. In a more complex framework, the *relata* appropriate for semantic evaluation may include, together with possible worlds, a temporal parameter: for instance, 'the President of the United States' may denote Bush with respect to a given possible world and a certain time, but Bill Clinton with respect to that world and another time span.

Let me refer to the semantic features for the aforementioned expressions as their semantic value: so, the semantic value of a sentence (with respect to a possible world and/or a time) is its truth value (with respect to that world and that time); the semantic value of a definite description (with respect to a possible world and/or a time) is its *denotatum* (with respect to that world and that time); and so on. In general, and leaving momentarily aside a few interesting complications, an expression is rigid with respect to a parameter k if it has the same semantic value across all

Rigid Designation

S Predelli, University of Nottingham, Nottingham, UK

Introduction

Rigidity is a semantic notion. Semantics studies the relationships between expressions in a language and (typically) extralinguistic items. Examples of semantically interesting features are the relationship between the name 'George Bush' and Bush, the individual to which it refers; the relationship between the sentence 'George Bush is a liberal' and falsehood, its truth value; and, at least in some views, the relationship between the definite description 'the President of the United States' and Bush, the individual it denotes.

The task of a semantic theory is not that of immediately assigning the aforementioned features to the appropriate expressions. For instance, that the sentence 'George Bush is a liberal' is to be assigned falsehood depends not only on the semantic traits of the expressions under analysis, but also on obviously extrasemantic facts having to do with Bush's political convictions. By the same token, that the *denotatum* of 'the President of the United States' is George Bush, rather than John Kerry or myself, also depends on extrasemantic facts having to do with the results of the latest presidential election. For this reason, the aim of a semantic theory is that of presenting *relativized* assignments of semantic features. For instance, what our theory may conclude is that 'George Bush is a liberal' is true with respect to all and only those parameters that provide a positive reply to the query about Bush's leftist tendencies, and that 'the President of the United States' denotes Bush with respect to all and only those parameters with respect to which Bush won the presidential elections. According to a customary approach, parameters of this type may be understood as possible worlds. In a more complex framework, the *relata* appropriate for semantic evaluation may include, together with possible worlds, a temporal parameter: for instance, 'the President of the United States' may denote Bush with respect to a given possible world and a certain time, but Bill Clinton with respect to that world and another time span.

Let me refer to the semantic features for the aforementioned expressions as their semantic value: so, the semantic value of a sentence (with respect to a possible world and/or a time) is its truth value (with respect to that world and that time); the semantic value of a definite description (with respect to a possible world and/or a time) is its *denotatum* (with respect to that world and that time); and so on. In general, and leaving momentarily aside a few interesting complications, an expression is rigid with respect to a parameter k if it has the same semantic value across all

*k*s. For instance, an eternally true sentence is temporally rigid: its truth value is constant across all times. Since in what follows I leave temporal considerations out of the picture, I employ the expression 'rigid' *tout court* as alluding to constancy of semantic value across possible worlds.

Names and Rigidity

Two kinds of singular designators, namely names and definite descriptions, have been singled out as paradigmatic of the rigid/nonrigid divide. As I hinted, typical definite descriptions such as 'the President of the United States' are nonrigidly associated with distinct *denotata* with respect to different possible worlds. But proper names such as 'George Bush' apparently rigidly persist in referring to Bush with respect to all possible worlds (or, at least, all possible worlds in which Bush exists; more on this *caveat* later). For instance, if you are interested in evaluating 'George Bush is wise' with respect to a counterfactual scenario as dramatically different from the actual world as you may like, what you need to consider is whether, given the collection of individuals that are wise in that scenario, Bush is one of them (see Kripke, 1980).

One possible source of confusion must be cleared from the outset: what is at issue is not the question of who happens to be called 'George Bush' in the scenarios under consideration: that in some merely possible world certain expressions may be endowed with a different meaning, and certain names may be used to refer to alternative individuals is of no relevance for our purpose. Similarly irrelevant is the possibility that, in our actual employment of 'George Bush', different individuals may be referred to by that name type.

Types of Rigidity

I wrote that typical definite descriptions behave nonrigidly. This does not entail that there may not be rigid definite descriptions. For instance, 'the positive square root of four' denotes the number two with respect to any possible world and is thus a rigid designator. It seems clear that this expression's rigidity derives not directly from its semantic behavior, but from the modal perseverance of the mathematical world. The description 'the positive square root of four' interacts with the parameter with respect to which it is evaluated as any other description would: a certain condition is being put forth, in this case that of being the positive square root of four, and an individual is selected on the basis of its ability to satisfy that condition. The description is, in a sense, semantically available for a nonrigid profile. Its rigidity is a result not of its semantic behavior, but of the response that alternative possible worlds provide: one and the same item, the number two, is inevitably being offered as the description's *denotatum*.

Saul Kripke refers to descriptions such as 'the positive square root of four' as rigid only *de facto*. Expressions such as proper names, namely expressions whose semantic profile presumably guarantees their rigidity, are classified as rigid *de jure* (Kripke, 1980). Note that in this understanding of the *de facto*/*de jure* distinction, not all rigid descriptions are rigid merely *de facto*. For instance, the description 'the actual President of the United States' rigidly refers to a certain individual by virtue of its semantic behavior, in particular by virtue of the meaning of the indexical expression 'actual' (see Kaplan, 1977; Lewis, 1970).

Thus far, I rested satisfied with the notion that a rigid expression has a constant semantic value across possible worlds, and, in particular, that a rigid designator designates the same individual with respect to any possible world in which that object exists (Kripke, 1980; see also Kaplan, 1977). When it comes to the decision about an expression's semantic value with respect to possible worlds in which that object fails to exist, two options may be entertained. In the terminology from Salmon (1981), a designator is **persistently** rigid iff it designates its *designatum x* with respect to any world in which *x* exists and designates nothing with respect to any world in which *x* does not exist. On the other hand, a designator is **obstinately** rigid iff it designates *x* with respect to every possible world, regardless of whether *x* does or does not exist in it.

Rigidity has played an important role in one of the central semantic debates during the seventies and eighties, having to do with descriptivist views of customary proper names, such as, presumably, Frege's and Russell's. If proper names are rigid but typical descriptions are not, so the story goes, proper names may not behave in the manner descriptivists envisage. (For a critical discussion of a descriptivist reply, to the effect that proper names are associated with rigid descriptions, see Salmon, 1981; Soames, 1998.) Other important themes linked to the notion of rigidity have to do with the hypothesis that natural kind terms, such as *tiger* or *gold*, also behave rigidly (see Kripke, 1980; for a detailed discussion of the difficulties in extending the classic definition of rigidity to kind terms, see Soames, 2002). Finally, the idea of rigidity and the distinct but related notion of direct reference occupy center stage in the semantic analysis of indexical expressions. (On the relationships between rigidity and direct reference, see Marti, 2003.) For instance, an indexical singular term such as *I* rigidly refers (with respect to a given context *c*) to

the agent of *c*, that is, at least in typical instances, to the person who is speaking. The notion that indexicals such as *I* behave rigidly, even though they are associated with a descriptive meaning, plays a crucial role in the classic arguments for the distinction between meaning and content or, in David Kaplan's classic vocabulary, between *character* and *content* (see Kaplan, 1977; Lewis, 1980).

Ritual and Religious Language

Definition and Varieties

The concept of ritual language presupposes a concept of ritual, a category beset by numerous definitional problems. At times it appears that the category of ritual has become a holding-area for all those forms of behavior to which we cannot attribute any utilitarian value. This has led both to confusion over the definition of ritual, and to a common pejorative evaluation of ritual as meaningless, as illustrated by the modern history of the theorization of this category. There is a line of influence that extends from Reformation polemics against traditional Catholic liturgical practices to 19th- and early 20th-century anthropologies characterizing magic as a survival from primitive culture (Tylor, 1903), as well as a mistaken theory and praxis outmoded by science (Frazer, 1951). Later sociological interpretations recovered a positive value for rituals by emphasizing the role that these play in constructing, reinforcing, and contesting the dynamics of social groups (Durkheim, 1965; Gluckman, 1954; Turner, 1977; Bourdieu, 1977; Lincoln, 1994). Due to their emphasis on social dynamics, and despite their frequent application of structuralist analysis to ritual processes, such interpretations have generally paid little attention to the specific forms of ritual language. However, other scholars have emphasized the performative or pragmatic dimensions of ritual (Tambiah, 1985), and occasionally conducted sophisticated semiotic analyses of ritual language (Sebeok, 1964; Silverstein and Urban, 1996). Taking all of these approaches into account produces a more coherent theory of ritual language.

There exist numerous terms for different types of ritual language. Each culture of course has its own terms. Common English terms are 'spell,' 'charm,' 'incantation,' 'chant,' 'prayer,' and 'glossolalia.' More recent, theoretical terms include 'performative utterance' (Austin, 1975), 'speech act' (Searle, 1969), and 'indexical icon' (Silverstein, 1993, 1998; Silverstein and Urban, 1996). Although by no means exhaustive, this list is representative, and it indicates some of the important variations among types of ritual language. Spells and chants are often formulaic and invariant, whereas glossolalia and certain forms of prayer are, at least ostensibly, spontaneous and improvised. Some forms of ritual language aim to achieve obviously practical objectives, whereas others, including some forms of prayer, do not. Historically, these very distinctions have informed some attempts to distinguish 'good' rituals from 'bad' or superstitious ones. During the Reformation, for example, Puritans objected to repeated and formulaic prayers, as well as to any form of magic. Perhaps the most common concept of ritual language, however, is a verbal formula of magical or at least pragmatic

the agent of *c*, that is, at least in typical instances, to the person who is speaking. The notion that indexicals such as *I* behave rigidly, even though they are associated with a descriptive meaning, plays a crucial role in the classic arguments for the distinction between meaning and content or, in David Kaplan's classic vocabulary, between *character* and *content* (see Kaplan, 1977; Lewis, 1980).

Definition and Varieties

The concept of ritual language presupposes a concept of ritual, a category beset by numerous definitional problems. At times it appears that the category of ritual has become a holding-area for all those forms of behavior to which we cannot attribute any utilitarian value. This has led both to confusion over the definition of ritual, and to a common pejorative evaluation of ritual as meaningless, as illustrated by the modern history of the theorization of this category. There is a line of influence that extends from Reformation polemics against traditional Catholic liturgical practices to 19th- and early 20th-century anthropologies characterizing magic as a survival from primitive culture (Tylor, 1903), as well as a mistaken theory and praxis outmoded by science (Frazer, 1951). Later sociological interpretations recovered a positive value for rituals by emphasizing the role that these play in constructing, reinforcing, and contesting the dynamics of social groups (Durkheim, 1965; Gluckman, 1954; Turner, 1977; Bourdieu, 1977; Lincoln, 1994). Due to their emphasis on social dynamics, and despite their frequent application of structuralist analysis to ritual processes, such interpretations have generally paid little attention to the specific forms of ritual language. However, other scholars have emphasized the performative or pragmatic dimensions of ritual (Tambiah, 1985), and occasionally conducted sophisticated semiotic analyses of ritual language (Sebeok, 1964; Silverstein and Urban, 1996). Taking all of these approaches into account produces a more coherent theory of ritual language.

There exist numerous terms for different types of ritual language. Each culture of course has its own terms. Common English terms are 'spell,' 'charm,' 'incantation,' 'chant,' 'prayer,' and 'glossolalia.' More recent, theoretical terms include 'performative utterance' (Austin, 1975), 'speech act' (Searle, 1969), and 'indexical icon' (Silverstein, 1993, 1998; Silverstein and Urban, 1996). Although by no means exhaustive, this list is representative, and it indicates some of the important variations among types of ritual language. Spells and chants are often formulaic and invariant, whereas glossolalia and certain forms of prayer are, at least ostensibly, spontaneous and improvised. Some forms of ritual language aim to achieve obviously practical objectives, whereas others, including some forms of prayer, do not. Historically, these very distinctions have informed some attempts to distinguish 'good' rituals from 'bad' or superstitious ones. During the Reformation, for example, Puritans objected to repeated and formulaic prayers, as well as to any form of magic. Perhaps the most common concept of ritual language, however, is a verbal formula of magical or at least pragmatic

effect. Therefore, the problem of how to understand claims for the efficacy of ritual, including its ability to bring about real-world objectives through the manipulation of words and other objects, looms large in any discussion of ritual language. This problem is underscored by the still prevalent pejorative designation of ritual, especially magic, as 'mumbo jumbo' or 'hocus pocus.'

Following Redfield (1956), a distinction can be made between the ritual languages of 'great' or civilizational and 'little' or folk traditions. (This parallels a similar distinction between 'official' and 'folk' traditions, except that official traditions are not always 'great' or civilizational.) Of course, both types can coexist within a single society. The distinction between these types of ritual language can have important consequences in defining social groups. (See 'Sociological Dimensions of Ritual Language' below.) There are broader resemblances among the ritual languages of some of the great traditions that distinguish them from those of most folk traditions. The verbal formulas or mantras of the Sanskritic tradition of Hindu Tantra in South Asia bear more resemblance to the spells of the Greek Magical Papyri, or to Kabbalistic formulas, than they do to Bengali folk mantras, despite greater geographical and cultural proximity to the latter. The main distinction from folk spells consists in the development of a more elaborate code, represented by increasingly intricate linguistic patterns, as exemplified by the extended palindromes of some Greek and Sanskrit spells. Such devices, which are difficult or impossible to recognize in an oral tradition, may reflect in part an increased reliance on writing, as well as the presence of esoteric traditions necessary for the elaboration of a code, although this last feature is of course also present in many oral traditions.

The distinction between oral cultures and cultures in which writing or printing has become dominant as a mode of communication is of great importance for ritual language. There is some evidence that the critique and decline of certain forms of ritual language may be associated with writing. The importance of poetic formulas as mnemonic devices and aids to performance in oral cultures has been recognized in recent decades (Lord, 1960). It has been argued further that writing not only replaces poetry as a technique of cultural transmission, but may even lead to a new, skeptical episteme critical of the irrationality of poetry (Havelock, 1963; Goody, 1977). The connection between poetry and ritual or magical language is sometimes reinforced in these critiques, making these issues relevant to an account of ritual language. (See 'Historical Dimensions of Ritual Language' below.)

Nonritual Religious Language

Although the focus of this article is primarily on ritual language, other types of religious language are properly described here in relation to ritual language. In religion as in every other domain of human culture, language plays a central role as the most important means of communication, a fact recognized in many religious traditions. Some well-known examples are the creation of the world through the power of God's speech in the Hebrew Book of Genesis, the identification of Jesus as the Word of God in the Christian Gospel of John, and the various cosmogonies developed in Hinduism from Vedic times onward in which speech is the agent or instrument of creation (Padoux, 1990). Many religious traditions acknowledge the power of the word by the formation of canons (Smith, 1982), especially of the written variety called scripture. Although canon and codification are broader phenomena that have also been associated with modernity and colonialism, the specifically religious conflict between the Peoples of the Book and the idolaters had special significance for the historical development of ritual languages. (See 'Historical Dimensions of Ritual Language' below.)

Myth is another subcategory of religious language that has received much attention from linguists and anthropologists, especially following Lévi-Strauss's application of structuralist linguistic theories to myth. The fact that myths are a form of language, whereas ritual comprises a range of behaviors not limited to the verbal, may explain why structuralist analyses of ritual came later than those of myth. The identification of myth and ritual as fundamental categories of religion has precipitated a number of theories concerning the relation between these categories. The so-called myth and ritual school developed the idea that myth derives from and attempts to explain a preexisting ritual complex. On the other hand, Eliade (1954) argued that myth describes the actions of the gods or ancestors at the beginning of time, and that ritual refers to myth as the archetype for human actions in the present. As illuminating as these interpretations occasionally are, it is important to note that many rituals are largely independent from myth, and *vice versa*.

Structure and Function of Ritual Language

For purposes of analysis, it is useful to separate the structural or formal aspects of ritual language from their functional aspects or pragmatic effects, although the goal is to arrive at a better understanding of the

contribution of form to function. The formal differences of ritual from ordinary language were described in great detail by Malinowski in his study of Kiriwinian (Trobriand Islands) spells (Malinowski, 1935). These spells exhibited a "coefficient of weirdness" that came from their use of archaisms and apparently meaningless forms, onomatopoeias, repetitive and rhythmic chanting, extensive metaphors, and allusions to myth. Malinowski argued that many magic words were 'meaningless,' but also that the various stylistic features of spells somehow supported the "creative metaphor of magic," or the belief that ritual is able to bring about its intended result. Working in part from the same data, Tambiah (1985) argued for the persuasive or performative function of a number of these stylistic features. However, his model emphasized the semantic figures, especially the metaphors and metonyms, of ritual language, rather than its rhythmic form. It is this latter feature that raises what might be called the 'abracadabra problem': how do we explain the prevalence in ritual language of so many apparently nonsensical, repetitive sounds, as evidenced not only in numerous ritual traditions (e.g., the Ephesian Words beginning *aski kataski*. . . found in many Greek spells, and the Hindu Tantric seed (*bīja*) mantras such as *hrīm klīm śrīm*), but also in pejorative terms such as 'mumbo jumbo'? The dismissal of such forms as meaningless (e.g., by Staal, 1996) does not account for their frequency of occurrence in ritual language. For any particular term such as 'abracadabra' or 'hocus pocus,' one may be able to provide a probable etymon of which the magical word is a corruption. However, this does not explain how, as actually used in ritual discourse, such magic words function.

One possible explanation for such stylistic features is that they serve primarily to differentiate ritual from ordinary language. This hypothesis accords with one of the fundamental insights of linguistic structuralism: namely, that any distinction in the value of a linguistic sign depends upon an associated distinction in its form. The principle of binary opposition discovered by Saussure may also serve at the level of genres to distinguish ordinary language, on the one hand, from poetry, literature, or ritual discourse, on the other. Indeed, the thesis that poetry represents simply a deviation from ordinary language has been articulated within structuralist poetics. This thesis is paralleled within ritual studies by Bell's emphasis on techniques or strategies of ritualization that serve to differentiate ritual from ordinary discourse or behavior (Bell, 1992). These theories may account for the fact that many forms of ritual language are incomprehensible to their hearers and even, on occasion, their speakers. In such cases, it is not any semantic content, but rather the formal differences of the ritual medium that constitute its message. The preservation of the mass in Latin long after that language had ceased to be a vernacular, and the dissemination of Sanskrit mantras in transliterated rather than translated form as far as Japan, reflect a more basic strategy to distinguish ritual from the mundane or profane, as well as to conserve the prestige of origins, and to create mystery.

An objection to such theories is that they fail to explain the prevalence of poetic repetition and other particular devices, including metaphor and metonymy, in the ritual languages of different cultures. If ritual were only a matter of constructing difference, then any deviation from ordinary language would do, and we should expect randomness in the variety and distribution of stylistic features in ritual language. What we often find instead is an extreme form of the poetic function as defined by Jakobson (1960): a projection of equivalence into the sequence of language, manifested as versification, rhyme, semantic repetition, etc. These devices are especially prevalent in magic. What explains this phenomenon?

Silverstein has shown that ritual performance often constitutes an indexical icon, in which forms of repetition or resemblance in the text of a ritual increasingly point to their context. This is similar to the mechanism of (nonverbal) sympathetic magic, which, as theorists from Tylor and Frazer onward have noted, interprets a relation of similarity (metaphor, icon) or contiguity (metonym, index) between the ritual and its intended result as a causal (indexical) relation (cf. Leach, 1976). Just as repeatedly poking a pin into the left arm of a voodoo doll is supposed to bring about a corresponding injury in one's intended victim, or pouring water on the ground is supposed to bring rain from the sky, the poetic imitation in ritual language is supposed to point beyond itself to bring about a real-world result. In the case of many folk charms, the accumulation of rhythmic sound appears to be the mechanism by which ritual language increasingly signals its intended result. An example is "Rain, rain, go away/Come again some other day." Resemblances (icons) on the phonetic level of the text of the ritual reinforce the ritual as a signal (index) of a goal in its context: in this case, the cessation of rain (cf. Sebeok, 1964).

As compared with such folk charms, the mechanism of Hindu Tantric mantras is more complex. Mantras often are made effective (*siddha*) by being converted into palindromic diagrams of several processes of creation, including the cosmogony conceived as a cycle of evolution and involution, and sexual reproduction (Yelle, 2003). Ritual performance of the mantra both imitates and instantiates the creative power of speech as the source of the cosmos. Syllables of special power

called seeds (*bīja*) surround the central portion of the mantra, which often declares its real-world goal, such as subjugating an enemy. By verbally tracing the sequence of creation, the mantra leads up to and indexes this real-world goal, symbolically bringing it into existence.

Such examples suggest that at least some types of ritual language do not operate by reinforcing a difference between ritual and ordinary language, but rather by attempting to overcome any difference or gap between ritual language and its context of use. Ritual tries to construct a language that is directly connected to, and even capable of influencing, reality. This hypothesis appears to account for two additional devices found in ritual language. Many spells enumerate an entire paradigm class, which may be a set of objects such as body parts (cf. Tambiah, 1985), but also a set of rhyming words or, in the case of Tantric mantras and Greek spells, all or a portion of the sound system or alphabet. Such extreme forms of repetition augment ritual language as an indexical sign of its goal. This pointing function is further illustrated by so-called counting-out spells which, by counting from ten down to zero (or, in the case of some Greek spells, removing all of the letters of the spell one by one), signal the end and accomplishment of the spell.

These examples suggest a different evaluation of the relation between 'emic' (culture-internal) and 'etic' (comparatively cross-cultural) theories of performance or pragmatic function. From an emic perspective, the forms of poetic imitation employed in ritual language appear to construct a language that bears an especially close indexical relation to nature. However, from an etic or outsider's perspective, such devices serve primarily to construct a persuasive illusion of a perfect and effective language.

These considerations require us to reevaluate what is meant by ritual performance. In recent decades, following Austin's definition of a performative utterance and Searle's refinement of this with the notion of a speech act, the theory that ritual is a form of performance has gained broader currency (Tambiah, 1985). Austin's original concept has been applied to many cases, including magic, to which it did not on its own terms claim to extend. This is of course not a reason for automatically dismissing such applications. However, it is a reason for revisiting the concept of a performative, especially as applied to ritual.

Austin recognized that many utterances accomplish something through the simple fact of their being uttered. Statements such as "I christen this ship" or "I thee wed" do not merely **say** something, but **do** something. Linguists would agree that such statements have pragmatic and not merely semantic value. To this extent, Austin's concept of a performative represents a valuable corrective against the semantic bias of much modern philosophy, with its emphasis on propositional content. As we have seen, a similar semantic bias also informs many interpretations of ritual language as meaningless.

However, there are a few problems with Austin's theory. First, his concept of performance or pragmatic function is too restrictive. If the conditions of its use are fulfilled, a performative utterance accomplishes something through the mere act of utterance: mutual promises may themselves constitute a valid legal contract. On the other hand, many rituals, especially of the magical variety, point to some real-world goal, such as the beginning or cessation of rain, something that may or may not occur automatically upon the completion of the ritual. The fiction may be that ritual achieves these goals *ex opere operato*, but the reality is otherwise. The concept of performativity or pragmatic function must be broadened, if applied to such cases, to allow that ritual sometimes performs by constructing a persuasive illusion of efficacy.

A second problem with Austin's theory is that he omitted any account of the contribution of poetry to ritual performance. In his view, performatives, like other ceremonial doings, were purely conventional in form, formulaic. On the contrary, we have already seen that many types of ritual language employ poetry in order to augment if not to bring about the performative or pragmatic function of ritual. Some historical roots of Austin's neglect of the poetry of ritual are examined below.

Sociological Dimensions of Ritual Language

Ritual languages may not be distributed evenly within a society. Like other ritual techniques, they are often the property of particular social groups. Individuals who are not members of these groups may be denied training in the techniques of ritual performance, or access to the cultural code that permits the full comprehension of the ritual, or even the opportunity to observe a ritual performance. Esotericism results whenever there is a deliberate and sufficiently rigorous restriction of access to ritual to an in-group of initiates. Public rituals, of course, may also reinforce divisions within the social order. Proprietary rituals have a role in defining social groups, for example in male and female ritual societies. In some cases, the rituals with the greatest cultural prestige – those of the 'official' tradition(s) – are reserved for male practitioners, and women may develop expertise in other, folk rituals, such as trance, mediumship, possession, and witchcraft, which are understood to exist at a less

important level of the social structure. In Catholicism the performance of the sacraments is reserved for ordained males. In Hindu Tantra, there are numerous prohibitions against the use of the sacred syllable 'om' by women or servants (*śūdras*, the lowest division of the social order), who are instead enjoined to substitute some other syllable. Given the symbolic significance of 'om' as the primordial utterance of the first man, which ushered in creation, these ritual injunctions also encode the idea that women and lower-class individuals should be denied access to sacred, effective speech: they are made (ritually) voiceless.

Sometimes ritual languages may be used not to reinforce the social order, but to contest one's position within, or criticize, or even overthrow that order. Examples are Radcliffe-Brown's joking relationships and Gluckman's rituals of rebellion (Radcliffe-Brown, 1952; Gluckman, 1954). Such rituals are often just a way of blowing off a little steam. Moreover, Bloch (1989) pointed out that the more stereotyped, formalized, and scripted ritual discourse becomes, the more it tends to reinforce conventional authority, by rendering deviation from the script in performance less likely. However, even rigidly scripted rituals may get out of hand. Lincoln's account of the discursive construction of authority allows for just such occasions of corrosive discourse. These accounts raise difficult questions of agency, or of the relation between individuals and social structures. Bourdieu's concept of habitus as the flexible cultural structures that both condition individual responses, and are susceptible to strategic manipulation by individuals, seeks to address this fundamental issue.

Questions of agency and intentionality are also of paramount importance in connection with such rituals as trance, mediumship, and possession, where there is a displacement or denial of the ritual practitioner's agency. Perhaps the most well-known example of ritual language of this sort is glossolalia, in which the Holy Spirit speaks through the practitioner in what is understood to be an unscripted performance. Even these 'spontaneous' forms, however, are learned social behaviors that exhibit phonological constraints reflecting the natural languages of their users (Samarin, 1972; Goodman, 1972).

Relation between Verbal and Other Modes of Ritual

Earlier tendencies to focus on myth, due its linguistic medium and consequent assumed meaningfulness, to the relative neglect of certain nonverbal forms of ritual are now in the first stages of reversal. More attention is now being given to such media as dance. However, these studies have to contend with a basic defect of ethnographic method: the lack of any system of notation of bodily movement that is both accurate and widely used. This parallels the problem of recording and interpreting the special modes of pronunciation or chanting of ritual language. Although tape recordings can capture such forms in the raw, there is still a significant difficulty in the recognition and interpretation of their distinctive features from analytic study of notated transcripts.

Certain stylistic features, such as imitation, appear to transcend the divide between the verbal and nonverbal modes of ritual. Aristotle noted that the modes of imitation (mimesis) are different in different arts: in music, rhythm and harmony would be the modes employed (*Poetics* 1.1), whereas in painting, color and line would presumably be the relevant modes. The concept of mimesis itself has been traced to the ritual dances that formed the basis of Greek tragedy (Koller, 1954), which suggests that the original forms of imitation were not verbal at all, but gestural. The use of imitation in the nonverbal dimensions of ritual was documented already in Frazer's account of sympathetic magic. As previously described, ritual language often uses poetic imitation in a similar way. The Hindu Tantric womb sign (*yonimudrā*), which iconically depicts the embrace of the womb, is a gestural equivalent and substitute for the verbal enveloping of the mantra with magic syllables. Both types of icon diagram basic processes of creation, including sexual intercourse. In such cases, verbal and nonverbal forms of ritual behavior may carry an identical meaning and pragmatic function. The fact that certain semiotic patterns transcend the divide between language and movement reinforces the conclusion that movement shares with language a cultural and cognitive basis.

Ritual frequently coordinates verbal and nonverbal behaviors through superimposition, simultaneity, and sequencing. The entextualization of the ritual performance (cf. Silverstein and Urban, 1996) constructs a diagram or diagrammatic icon in which speech and movement are fused and reciprocally imitative. For example, in Hindu Tantra, the syllables of the mantra may be laid out on the body of a ritual practitioner, or visualized as moving back and forth within the body, as a representation of the processes of creation otherwise verbally diagrammed by the mantra when spoken.

If the same functions may be served alternatively by either verbal or nonverbal modes of ritual, then why should the coordination of these modes be so frequent? One of the characteristics of ritual is that it builds in redundancies that attract attention or otherwise heighten the communicative force of its message. These redundancies may occur not only within but

across semiotic modes. Bloch (1989) has suggested further that the accumulation of "symbols, song, dance, and features of articulation" within ritual discourse is a way of enhancing its formality and consequent reinforcement of traditional authority.

Historical Dimensions of Ritual Language

The historical or diachronic dimensions of ritual language have received less systematic consideration than its structural or synchronic dimensions. This is in part due to the emphasis within modern linguistics on the study of language as a holistic system. Saussure famously drew a distinction between the system of a language (*langue*) and its instantiation in speech events (*parole*). Yet whether modern students of language choose to focus on the former or, especially through real-time discourse analysis, the latter, the end result is the same: historical transformations in linguistic practices and emic theories of language are largely left out of account.

This neglect presents a particular problem for the understanding of ritual language. One important historical development in linguistic practices is a diminution, within certain domains of certain cultures, of the poetic forms and pragmatic functions associated with ritual. We must be careful here to replicate neither the nostalgic associations of pre-modern folk culture with poetry promulgated by some Romantics, nor the triumphal evolutionary accounts of the replacement of magic by science advanced by early anthropologists. However, there is a great deal of evidence that, at some point in the past, the nexus of poetry and magic was more prominent than it is now. Grimm's study of poetic parallelisms in early Germanic law affords some examples (Grimm, 1957). Rhythmic formulas such as "unbidden and unbought," or "to have and to hold," were common in early English law as well, where they contributed to the binding force of many vows, oaths, and declarations. What happened to such formulas and the mode of ritual that they represented? One answer is that post-Enlightenment modernity has emphasized literalism, or plain speaking and the semantic content of language, at the expense of both poetry and magic. Poetry has been reduced to a mode of entertainment, and few people believe in what goes for magic these days. The semantic bias has reinforced the view of ritual as meaningless. However, these are only observations, not explanations.

One explanation that attempts to account for the perceived decline in formalized ritual is Tambiah's concept of "ritual involution." The very features that contribute to the performative aspects of ritual, such as increased formalization, over time may lead to a rejection of that ritual as rigid and empty. Certainly both attitudes toward ritual formalization—positive and negative—may be observed. However, Tambiah's concept provides no diagnosis of the conditions that would result in one attitude rather than the other, diametrically opposed attitude being adopted. Moreover, he has framed ritual involution largely as a subjective rather than as an historical process, despite the fact that the pejorative evaluation of ritual as stereotyped and meaningless is especially prominent in modernity, and must therefore be given an historical explanation.

Another explanation, mentioned at the outset of this article, builds from recent studies on the effects of the transition from an oral culture to one based on writing (Havelock, 1963; Goody, 1977). According to what we may call the literacy hypothesis, poetry was necessary in oral culture as a mnemonic device. Writing not only replaced this function of poetry, but introduced an emphasis on literal meaning and a skepticism regarding certain modes of rhetoric. However, such theories do not fully explain why the obsolescence of poetry as a mnemonic technique should have led to such pejorative evaluations. Nor do they account for the fact that, in the prime example addressed by the literacy hypothesis, that of ancient Greece, the focus of such criticisms was on the persuasive rather than the mnemonic function of poetry. The persuasive or rhetorical function of poetry established its association with magic for both the sophists and their opponents, the philosophers (see Gorgias, *Helen*; Plato, *Republic*, Book 10). As we saw, it is this crucial nexus of poetic form and persuasive function that characterizes many rituals.

Apart from ancient Athens, another important moment in the development of ritual language occurred during the Reformation. The Protestant emphasis on the literal interpretation of a canon of scripture, and on translation into the vernacular, led to the demise of certain older liturgical forms. This represented not merely a modern rationalization of religion, but also a recrudescence of certain ancient Jewish and Christian religious ideas, including especially the prohibition against idolatry. Christ prohibited the use of "vain repetitions" in prayer (Matt. 6:7, Authorized Version [1611]). Some Puritans associated this prohibited practice with the worship of idols, especially for magical purposes, and with attempts to persuade the deity rhetorically (e.g., Calvin's *Institutes*; Matthew Henry's *Commentary*). They applied this prohibition against repetitive or formalized prayers employed by Catholics and also by the established Church of England. Thomas Cranmer, the author of the *Book of common prayer* (1549), explained in his

introduction to that work that he sought to eliminate many superstitious rituals, including "vain repetitions," from the liturgy. Although he did not go as far as some Puritans would have liked, one consequence of his effort was that more poetic versions of the marriage oath disappeared. For example, the wife's promise "to be bonour and buxom at bed and at board" was replaced by the now familiar "to love, cherish, and to obey." The sole remaining rhythmic (as opposed to semantic) parallelism was the declaration "to have and to hold," an old formula of ownership attested in both English and German law. Although the critique of "vain repetitions" had not been applied directly against such rhythmic formulas in the marriage vow, it contributed to a literalism that ultimately caused the demise of these formulas, as well as of Latin as a ritual language. The irony is that Austin's own prime example of a performative—the declaration "I do" (sic) during the marriage ceremony—unwittingly continued this repression of the poetry of ritual, by failing to acknowledge the historical context and development of the marriage oath.

As in ancient Greece, the literacy hypothesis appears to account for some of these developments. It has been suggested that the poetic devices of early English law served a mnemonic function in an oral culture. The Reformation, leading to the *Book of common prayer*, reflected not the discovery of alphabetic writing as in ancient Greece, but instead a culture of printing based on the technological innovation of movable type in 15th-century Europe. The result in each case was similar: an increase in literacy, and in literalism. However, in each case these developments were facilitated not only by writing, but also by polemics against the nexus of poetic form and persuasive function constituted in ritual.

It is important to recognize that religion stands on both sides of this debate over ritual language, both as the matrix for traditional rituals and as the source of certain criticisms of these rituals as idolatry. A survey of the development of linguistic empiricism in Britain reinforces this conclusion. Following Francis Bacon's (1561–1626) attack on "idols of the marketplace," John Locke (1632–1704) excoriated the habit of "taking words for things," or inferring from the existence of a name to the existence of the thing named. Jeremy Bentham's (1748–1832) critique of such "fictions" drew explicitly on religious prohibitions against idolatry. Among the fictions he sought to proscribe were ritualized oaths used in the courtroom. As late as the second half of the 19th century, Friedrich Max Müller's (1823–1900) theory of myth as a "disease of language" still reflected such criticisms of verbal idolatry. Nor were these developments confined to England. In colonial India, the gospel verse against "vain repetitions" was used to proscribe the repeated chanting of mantras. These polemics influenced the religious literalism of such Hindu Reformers as Rammohun Roy (1772?–1833) and Dayananda Sarasvati (1824–1883), who championed the canon of the Vedas against such forms of idolatrous ritual.

In conclusion, a brief historical survey of certain developments regarding ritual language underscores the need to consult both historical and anthropological data when proposing a theory of ritual language. As linguists, we must be concerned not only with the elaboration of a neutral science of the laws of language, but also with the legislations of language made by particular cultures at particular times, that determine which among the possible forms and functions of language will be permitted or prohibited.

Robert Henry Robins, known as Bobby to his friends and colleagues, is best remembered for his *A short history of linguistics*, which was originally published in 1967 and entered its 4th and final edition in 1997. Robins was a great advocate for the study and teaching of the history of linguistics, and while he contributed to research in a number of areas of linguistics, it was the study of the history of the discipline that formed the backbone to his life's work. His 1951 book *Ancient and medieval grammatical theory in Europe with particular reference to modern linguistic doctrine* grew out of a series of lectures he was persuaded to give by J. R. Firth at Birkbeck College, London, in 1950. Later historiographical work extended to studies of the London School, of which he was himself a part, the 16th-century grammarian of English William Bullokar, the 18th-century philosopher of language, Étienne Bonnot de Condillac, the 18th-century orientalist Sir William Jones, and the 19th-century Neogrammarians, as well as to reflections on the nature of the subject itself. In his last book (Robins, 1993) he returned to the classical interests with which he started.

His research energies were not limited to the classical languages and the history of linguistics, however. In 1951 he worked on the Californian language Yurok and published on this language throughout his career as well as on the Javan language Sundanese (Sunda). His interest in endangered languages resulted in the book *Endangered languages* (Robins and Uhlenbeck, 1991), published under the auspices of the Comité International Permanent de Linguistes, of which he was president. Alongside the *Short history*, the other work with which Robins's name is particularly associated, is his *General linguistics: an introductory survey* (1964; 4th edn., 1989). As lecturer, then reader,

Role and Reference Grammar

R D Van Valin, Jr., University at Buffalo, The State University of New York, Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Role and Reference Grammar (RRG) (Van Valin, 1993a, 2005; Van Valin and LaPolla, 1997) grew out of an attempt to answer two basic questions: (i) what would linguistic theory look like if it were based on the analysis of languages with diverse structures such as Lakhota (Lakota), Tagalog, and Dyirbal, rather than on the analysis of English?, and (ii) how can the interaction of syntax, semantics and pragmatics in different grammatical systems best be captured and explained? RRG takes language to be a system of communicative social action, and accordingly, analyzing the communicative functions of grammatical structures plays a vital role in grammatical description and theory from this perspective. It is a monostratal theory, positing only one level of syntactic representation, the actual form of the sentence. The overall organization of the theory is given in **Figure 1**.

Central Concepts of the Theory

Clause Structure

RRG rejects the standard formats for representing clause structure (grammatical relations, X-bar syntax), because they are not universal and hence necessarily impose aspects of structure on at least some languages where it is not appropriate. The RRG conception of clause structure, the layered structure of the clause (LSC), is made up of the nucleus, which contains the predicate(s), the core, which contains the nucleus plus the arguments of the predicate(s), and the clause. Syntactic arguments occurring in the core are referred to as core arguments, and they may be direct or oblique. Direct core arguments are those not marked by an adposition, in languages such as English and German, or those marked by direct cases (nominative, accusative, dative or ergative, absolutive, dative) in case-marking languages like Russian or Dyirbal. Oblique core arguments are marked by adpositions or oblique cases, e.g., instrumental and locative. Modifying each level of

Central Concepts of the Theory

Clause Structure

RRG rejects the standard formats for representing clause structure (grammatical relations, X-bar syntax), because they are not universal and hence necessarily impose aspects of structure on at least some languages where it is not appropriate. The RRG conception of clause structure, the layered structure of the clause (LSC), is made up of the nucleus, which contains the predicate(s), the core, which contains the nucleus plus the arguments of the predicate(s), and the clause. Syntactic arguments occurring in the core are referred to as core arguments, and they may be direct or oblique. Direct core arguments are those not marked by an adposition, in languages such as English and German, or those marked by direct cases (nominative, accusative, dative or ergative, absolutive, dative) in case-marking languages like Russian or Dyirbal. Oblique core arguments are marked by adpositions or oblique cases, e.g., instrumental and locative. Modifying each level of

Figure 1 Organization of role and reference grammar.

Figure 2 The layered structure of the clause.

the clause is a periphery, which contains adjunct modifiers, both phrasal (PPs or clauses, modifying the core and clause) and nonphrasal (adverbs, modifying all three layers). These aspects of the LSC are universal.

Some language have a precore slot (PrCS), which is the position of WH-words in languages such as English and Icelandic, and a left-detached position, (LDP), which is the position of the preclausal element in a left-dislocation construction. In addition, some verb-final languages have a postcore slot (PoCS) (e.g., Japanese; Shimojo, 1995), and some languages also have a right-detached position (RDP), which is the position of the postclausal element in a right-dislocation construction. Each of the major layers (nucleus, core, clause) is modified by one or more operators, which include grammatical categories such as tense, aspect, modality, and evidentiality. The LSC applies equally to fixed word-order and free word-order languages, to head-marking and dependent-marking languages, to languages with and without grammatical relations. It is assumed that noun phrases and adpositional phrases have a comparable layered structure; operators in the NP include determiners, quantifiers and adjectival and nominal modifiers. In the formal representation of the LSC, operators are represented in a distinct projection of the clause from the predicates and arguments (the constituent projection). This is presented in Figures 2–5. In Figure 2, the peripheries have been omitted from this diagram for the

Figure 3 The LSC in English.

sake of simplicity. In Figure 3, *did* is labeled both tense and IF in the operator projection, because the position of the tense operator signals illocutionary force in English: core-medial tense signals declarative IF, core-initial (precore) tense signals interrogative IF, and the absence of tense in a matrix core signals imperative IF.

The operator projections of the clause have been omitted in Dyirbal (Dixon, 1972) and Lakhota examples. The Dyirbal and English sentences in Figure 4 are translations of each other. The lines connecting the determiners to the head nouns are the operator projection within the NP, analogous to the operator

Figure 4 The LSC in Dyirbal and English.

Figure 5 The LSC in Lakhota (head-marking) and English (dependent-marking).

projection within the clause, as in Figures 2–3. In head-marking languages such as Lakhota, the bound pronominals on the verb are considered to be the core arguments; overt NPs are within the clause in apposition to them. Note that despite the differences between the three languages in Figures 4–5, comparable structural relations, e.g., core argument and peripheral adjunct, are represented in the same way. It should be noted that these representations are not abstract, unlike relational networks or functional structures; they are intended to be concrete, in the sense that they should represent the actual form of the sentence, including the linear sequence of its constituent elements and their morphological properties. The representation may be abstract with respect to phonology or morphophonology, e.g., the output could be in terms of abstract morphophonological units rather than concrete phonetic ones.

Representations of constituent projections such as these should be viewed as syntactic templates, the inventory of which in a language constitutes an important component of its grammar. It may be termed the syntactic inventory and complements the lexicon.

The three central components of the LSC also turn out to be the three fundamental building blocks of complex sentences in human language. The unmarked pattern for the construction of complex sentences involves combining nuclei with nuclei, cores with cores, clauses with clauses, or sentences with sentences. These are called levels of juncture in RRG, i.e., nuclear juncture, core juncture, clausal juncture, and sentential juncture. Sentential junctures are complex constructions made up of multiple sentences, while clausal junctures involve sentences containing multiple clauses. Examples of nuclear junctures from French, English, and Mandarin Chinese are given in (1) and the representation of (1a) is in Figure 6. Justifications for these structures can be found in Van Valin (2005).

(1a) Je ferai manger
1sg make.FUT eat
les gâteaux à Jean.
the cakes to John
'I will make John eat the cakes.'
[two nuclei, *faire* and *manger*, in a single core]

(1b) John forced open the door.
[two nuclei, *push* and *open*, in a single core]

(1c) Tā qiāo pò le yī ge fànwǎn
3sg hit break PRFV one CL bowl
'He broke (by hitting) a ricebowl.'
[two nuclei, *qiāo* 'hit' and *pò* 'break', in a single core] (Hansell, 1993)

Core junctures involve two or more cores (which may themselves be internally complex) in a clause.

Figure 6 The structure of (1a).

Figure 7 The structure of (2a).

Examples from French, English, and Mandarin are given in (2), and the structure of (2a) is presented in Figure 7. In this type of core juncture, the two cores share a core argument; sharing a core argument is defined formally in terms of the linking algorithm mapping syntactic and semantic representations into each other.

(2a) Je laisserai Jean manger les gâteaux.
1sg let.FUT John eat the cakes
'I will let John eat the cakes.'

(2b) I ordered Fred to force the door open.

(2c) Tā jiāo wǒ xǐe zì
3sg teach 1sg write characters
'She teaches me to write characters.'

Of equal importance in the RRG theory of complex sentences is the set of possible syntactic and semantic relations between the units in a juncture; the semantic relations are discussed in a related article (*see* **Semantics in Role and Reference Grammar**). The syntactic relations between units are called nexus relations in RRG. Traditionally, only two basic nexus relations are recognized, coordination and subordination. Subordination is divided into two subtypes, daughter subordination and peripheral subordination. They are illustrated in Figure 8.

The embedded clause in the first sentence is a daughter of the core node, while in the second the embedded clause is an adjunct in the periphery modifying the core.

In addition to distinguishing two types of subordination, RRG, following Olson's (1981) analysis of clause linkage in Barai (a Papuan language), posits a third nexus type: co-subordination, which is an essentially tight, dependent coordination. The dependence is operator dependence; that is, in co-subordination, the units obligatorily share one or more operators at the level of juncture. In the Mandarin example in (2c), aspect obligatorily has scope over both nuclei,

Figure 8 Daughter and peripheral subordination at the core level in English.

and therefore the nexus is co-subordination. This is represented as in Figure 9.

The following examples from Turkish (Watters, 1993) illustrate obligatory operator sharing and the lack of it in Turkish core co-subordination and coordination, respectively. The term 'coordination' here is being used for an abstract linkage relation referring to a relationship of equivalence and operator independence at the level of juncture. It is distinct from conjunction, which is a construction type of the general form X conj Y, which may be one of the formal instantiations of coordinate nexus (Figure 10).

Figure 9 Nuclear co-subordination in Mandarin.

(3a) Core co-subordination
Gid-ip gör-meli-yiz.
go-CMPL see-MODAL-1pl
'We ought to go and see.'

(3b) Core coordination
Müzik dinle-yerek, uyu-yabil-ir-im.
musiclisten-CMPL sleep-MODAL-AOR-1sg
'While listening to music, I can sleep.'

In (3a), the modal operator *-mElI-* 'ought' has scope over both cores, and therefore the nexus is co-subordinate; in (3b), on the other hand, the modal operator *-yAbIl-* 'able' has scope only over the final core, hence coordinate nexus. The following sentences from Kewa (Franklin, 1971) are a minimal triple for the three nexus types at the clause level.

(4a) Coordination
Nipú ípu-la pare
3sg come-3sg PRES but
ní paalá na-pía
1sg afraid NEG-be.1sg PRES
'He is coming, but I am not afraid.'

Figure 10 Turkish core junctures.

(4b) Co-subordination
(Ní) Épo lá-ri épa-wa
(1sg) whistle say-SIM.SS come-1sgPAST
'I whistled while I came,' or 'I came whistling.'

(4c) Subordination (peripheral)
(Ní) Épolá-to-pulu
(1sg) whistle say-1sg PRES-CAUSAL
irikai épa-lia
dog come-3sg FUT
'Because I am whistling, the dog will come.'

The four levels of juncture combine with the three nexus types to generate eleven possible complex sentence types; there is no sentential co-subordination, because there are no sentence-level operators, hence no possible operator sharing. In addition, both subtypes of subordination are possible at the clause, core, and nuclear levels. Not all of them are instantiated in every language. English, for example, has all except for nuclear subordination and coordination. The juncture-nexus types found in a language may be realized by more than one formal construction type; for example, both *Mary sat playing the guitar* and *Robin tried to open the door* instantiate core co-subordination, while both *For Sam to leave now would be a mistake* and *Lisa's losing her job shocked everyone* instantiate core subordination in English. The juncture-nexus types may be ordered into a hierarchy in terms of the tightness of the syntactic link between the units. This is given in Figure 11.

Figure 11 Interclausal syntactic relations hierarchy.

Semantic Structure

see **Semantics in Role and Reference Grammar.**

Focus Structure

The issue of the distribution of information in clauses and sentences was not addressed in early work in RRG, and Lambrecht's (1994) theory of focus structure has been integrated into RRG. Focus structure is the grammatical system that serves to indicate the scope of the assertion in an utterance in contrast to the pragmatic presupposition, and it is vital to the RRG analysis of many grammatical phenomena, e.g., constraints on pronominalization (Van Valin and LaPolla, 1997: Sect. 5.6), the interpretation of quantifier scope (Van Valin and LaPolla, 1997: Sect. 5.5; Van Valin, 2005: Sect. 3.6), the origin of VPs in languages that have them (Van Valin, 2005: Sect. 3.5), and extraction restrictions (Van Valin, 1995, 1998; Van Valin and LaPolla, 1997: Sect. 9.5; Van Valin, 2005: Sect. 7.6). An innovation in RRG is the distinction between the potential focus domain (PFD), i.e., the syntactic domain in the sentence where focus may fall, and the actual focus domain, i.e., the part that is focused in a particular sentence. Languages vary in terms of how the PFD is restricted, both in simple sentences and in complex sentences, and this variation underlies important grammatical

Figure 12 Predicate focus construction in English.

differences across languages (Van Valin and LaPolla 1997: Sect. 5.3, 1997: Sect. 7.6). The focus structure of an utterance is represented in a distinct projection of the clause from the operator and constituent projections; this is exemplified in Figure 12 for a predicate focus construction in English. Predicate focus is Lambrecht's term for the traditional topic-comment structure with a topical subject and a focal predicate; IU stands for basic information unit.

It is possible to represent all three projections in a single representation, as in Figure 13.

Grammatical Relations and Linking

In the earliest work on RRG, it was argued that grammatical relations such as subject and direct object are not universal and cannot be taken as the basis for adequate grammatical theories. In place of these notions, RRG employs the notion of privileged syntactic argument (PSA), which is a construction-specific relation and is defined as a restricted neutralization of semantic roles and pragmatic functions for syntactic purposes. The other arguments in a clause are characterized as direct or oblique core arguments; there is nothing in RRG corresponding to direct or indirect object.

PSAs may be characterized functionally as controllers or pivots. These two functions are exemplified in (5) and (6).

(5a) The tall man$_i$ hit William$_j$ and then ___$_{i/*j}$ ran away.
CONTROLLER PIVOT

(5b) William$_i$ was hit by the tall man$_j$ and then ___$_{i/*j}$ ran away.
CONTROLLER PIVOT

Figure 13 Clause structure with constituent, operator, and focus structure projections.

(6a) Bill persuaded the tall man$_i$ [___$_i$ to visit Sam].
CONTROLLER PIVOT

(6b) The tall man$_i$ was persuaded by Bill [___$_i$ to visit Leslie].
CONTROLLER PIVOT

Pivots are canonically the missing argument in a construction, as in (5) and (6), while controllers prototypically supply the interpretation for a pivot. It should be noted that there can be pivots without controllers, e.g., the extracted element in an extraction construction, and controllers without pivots, e.g., agreement controllers. A further contrast is highlighted in (5) and (6), the contrast between syntactic and semantic pivots and controllers. In the construction in (5), the controller is the first NP in the core, the traditional subject, regardless of its semantic function, whereas in the construction in (6), the controller is the undergoer argument, regardless of its syntactic status. Hence the controller in (5) is a syntactic controller, while the controller in (6) is a semantic controller. The types of pivots and controllers that the constructions of a language have are typologically very significant.

The linking system relating semantic and syntactic representations is summarized in Figure 14. Syntactic functions such as PSA and direct core argument represent the syntactic pole of the system, while logical structures represent the semantic pole. In every language with grammatical relations, there is an accessibility to PSA hierarchy for multiple-argument verbs; it is the Actor-Undergoer hierarchy interpreted from the Actor end, i.e., arg of DO > 1st arg of **do**′ > 1st arg of **pred**′ (x, y) > 2nd arg of **pred**′ (x, y) > arg of **pred**′ (x). In syntactically accusative constructions in languages such as English and German, the highest ranking argument is the default choice for PSA, whereas in syntactically ergative constructions in languages such as Dyirbal, it is lowest ranking argument that is the default choice. That is, in a syntactically accusative construction the unmarked choice for the PSA of a transitive verb is the actor, with the undergoer being a marked choice possible only in a passive construction. On the other hand, in a syntactically ergative construction, the unmarked choice for the PSA of a transitive verb is the undergoer, with the actor being a marked choice possible only in an antipassive construction. With an intransitive verb, the hierarchy is irrelevant, as the single macrorole functions as PSA regardless of whether it is actor or undergoer. It should be noted that in most languages the highest ranking argument is not the default choice for PSA but the only choice; such languages lack voice systems. (See Van Valin and LaPolla, 1997: Sect. 6.5)

Figure 14 RRG linking system.

An important consideration in PSA selection is whether it is restricted to macrorole arguments or not. In some languages, e.g., German and Dyirbal, only actor and undergoer arguments can function as the PSA of a construction; nonmacrorole direct core arguments can never function in this way. In others, e.g., Icelandic and Georgian, nonmacrorole direct core arguments can be selected to serve as the PSA of a construction. This contrast is seen most clearly in the status of dative NPs: in German they can never be true subjects, while in Icelandic they can.

Logical structures, macroroles and the hierarchy linking them are discussed in **Semantics in Role and Reference Grammar.** This part of the system is universal, in that there is very little cross-linguistic variation; this is the domain of lexical processes, as mentioned in that chapter. Where languages differ substantially is how macroroles and other arguments link into the syntax.

The reason the arrows in Figure 14 are double-headed is that the linking system works both from semantics to syntax and from syntax to semantics. A theory that could describe the linking from semantics to syntax only could be part of a language production system, but it would not be adequate for a comprehension system. In such a system, the parser, as an idealization, would take the input and produce a structured syntactic representation of it, identifying the elements of the layered structure of the clause and the cases, adpositions, and other grammatically relevant elements in the sentence. It is then the grammar's job to map this structure into a semantic representation, as the first step in interpreting it, and this is where the syntax → semantics linking algorithm is required. The details of the linking algorithms are given in Van Valin (2005).

Most of what counts as syntax in many theories, e.g., case assignment, agreement, and WH-movement, is handled in RRG in terms of the syntactic phase of the linking. The analysis of reflexivization in RRG follows the approach in Jackendoff (1992) and states the constraints for core-internal (clause-bound in other theories) reflexivization at the LS level, not with respect to the syntactic representation. RRG treats constructions as an important part of syntax, and they are represented in terms of constructional schemas. Cross-constructional and cross-linguistic generalizations are captured in terms of the general principles and constraints that constitute the linking algorithms, e.g., the Actor–Undergoer Hierarchy, the layered structure of the clause, and the PSA selection hierarchy. Only the idiosyncratic, language-specific features of constructions are represented in constructional schemas, which include syntactic, morphological, semantic and pragmatic (focus structure) information.

The linking in a WH-question in English is illustrated in Figure 15; the subscripts ACV and ACS stand for activated and accessible, and they refer to different cognitive statuses that a referent of the element may have; cf. Lambrecht (1994).

Constraints on WH-question formation and other extraction constructions are explained in terms of the interaction of focus structure and syntax, in particular in terms of restrictions on the potential focus domain (Van Valin, 1995, 1998, 2005).

Figure 15 Linking syntax and semantics in a simple sentence in English.

Some Implications of RRG

RRG illustrates one possible answer to the questions stated at the beginning, and it shows that it is possible to have a rigorous, typologically sensitive grammatical theory that takes semantics and pragmatics as central features.

With respect to cognitive issues, RRG adopts the criterion of psychological adequacy formulated in Dik (1991), which states that a theory should be "compatible with the results of psycholinguistic research on the acquisition, processing, production, interpretation and memorization of linguistic expressions" (Dik, 1991: 248). Van Valin (2004) relates RRG to psycholinguistic models of production and comprehension, and Bornkessel *et al*. (2004) provide an explanation for certain experimental results regarding German language processing using RRG. Guest (2003) presents a parser based on RRG that can parse a range of syntactic structures in both English and Dyirbal. Kailuweit *et al*. (2003) and Butler (2004) propose implementations of the RRG semantics-to-syntax linking algorithm for French and English, respectively.

The RRG approach to language acquisition, sketched in Van Valin (1991, 1994) and Van Valin and LaPolla (1997), rejects the position that grammar is radically arbitrary and hence unlearnable, and maintains that it is relatively motivated (in Saussure's sense) semantically and pragmatically. Accordingly, there is sufficient information available to the child in the speech to which it is exposed to enable it to construct a grammar. For example, Braine (1992) shows how a conception of clause structure very much like the layered structure of the clause could be constructed developmentally by the child. Rispoli (1991a, 1991b, 1994) shows how the lexical representations in RRG and the conception of grammatical relations could be learned. Bowerman (1990) provides evidence in favor of the view that rules linking syntactic and semantic representations of the type summarized in Figure 15 are learned, and Weist (1990) shows how the RRG theory of grammatical relations provides an explanation for the pattern of development of grammatical relations in children learning Polish. Weist *et al*. (2004) shows the importance of *Aktionsart* for the understanding of the acquisition of verbs. Van Valin (1994, 1998) puts forward an account of how some of the constraints on linking between syntactic and semantic representations in complex sentences (i.e., subjacency) could be learned. Certain otherwise problematic facts about the acquisition of WH-questions are explained in terms of RRG in Van Valin (1998, 2002). Van Valin (2001) explores the predictions made by the theory of clause linkage and presents evidence from seven languages in support of them.

Suzanne Romaine is a native of Massachusetts, USA and graduated from Bryn Mawr College in Pennsylvania with an A.B. in German and Linguistics. She traveled to Scotland on a Rotary International Foundation Fellowship and earned an M.Litt. in Phonetics and Linguistics from the University of Edinburgh, Scotland. She went on to earn her Ph.D. at the University of Birmingham, England in 1981. She has received honorary doctorates from the University of Tromsø, Norway in 1998 and the University of Uppsala, Sweden in 1999. She received the Canada Commonwealth Scholarship at the Ontario Institute for Studies in Education, University of Toronto. Romaine was named the Kristin Hesselgren Professor at the University of Uppsala for 1991–1992. This award is granted to an outstanding woman in the area of Humanities and is sponsored by the Swedish Research Council for the Humanities and Social Sciences. Since 1984, she has held the position of Merton Professor of English at the University of Oxford.

Romaine's research and publications span several areas such as sociolinguistics, language acquisition, bilingualism, and language loss. She has written an introductory textbook in the area of sociolinguistics, *Language in society* (1994), now in its second edition. Her chapter on sexism and language was expanded into the monograph *Communicating gender* (1999).

Romaine has conducted sociolinguistic research in the United Kingdom and in the Pacific region. She did fieldwork in Scotland on the language of working-class children. She has also done research in the area of bilingualism and language loss among the Punjabi speakers in England. Her textbook *Bilingualism* (1989; 2nd edition, 1995) relates much of her findings in these areas along with her work with language groups in Papua New Guinea. She has also written the book *Pidgin and Creole languages* (1988). Recently she has done research on Hawaiian Creole English. A sample of her work in this area can be found in a book she edited with John Rickford entitled *Creole genesis, attitudes and discourse* (1999).

Romaine has earned wide acclaim for her book on the state of language loss called *Vanishing voices*, written with Daniel Nettle (2000). The book has been translated into several languages, including Italian, French, Japanese, and Turkish. The volume earned the British Association of Applied Linguistics book-of-the-year award in 2001.

Roman *Ars Grammatica*

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Roman *ars grammatica* comprises Roman grammatical works written between the 3rd and the 6th century A.D. They are all intended as textbooks in the schools or as handbooks for teachers. The majority consists of descriptions of Latin morphology focusing on the word classes ('parts of speech'), but many of the works also include treatments of phonology, metrics, and stylistics. The standard textbooks of the Roman *ars grammatica* (especially Donatus's two grammars from the 4th century A.D.) were to form the basis for grammar teaching and grammar writing in Europe for more than a thousand years.

Roman *Ars Grammatica*

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Roman *ars grammatica* comprises Roman grammatical works written between the 3rd and the 6th century A.D. They are all intended as textbooks in the schools or as handbooks for teachers. The majority consists of descriptions of Latin morphology focusing on the word classes ('parts of speech'), but many of the works also include treatments of phonology, metrics, and stylistics. The standard textbooks of the Roman *ars grammatica* (especially Donatus's two grammars from the 4th century A.D.) were to form the basis for grammar teaching and grammar writing in Europe for more than a thousand years.

Background

The term *ars grammatica* means 'the art of grammar' and is a translation of Greek *technê grammatikê* with the same meaning. It is also likely that the Roman *ars grammatica* originated from the Greek genre (*see* **Dionysius Thrax and Hellenistic Language Scholarship**), but owing to the lack of surviving Greek grammatical texts and the dating problems within Greek linguistics, the exact nature of the connection between the two grammatical traditions remains unclear.

Just as in the Greek world, the Roman grammatical textbooks are designed for providing a metalanguage and a method for analyzing those literary texts (mainly metrical texts like the works of Homer and Virgil), which were used as the principal textbooks in the schools. Gradually, however, the textbooks became more linguistic, and literary considerations faded into the background. There are two likely reasons for this development:

1. The increasing divergence between the spoken and written language created a need for teaching a standardized literary language in the schools.
2. The establishment of an organized school system combined with a professionalism among the teachers, who preferred a fixed curriculum.

The works labeled *ars grammatica* cover a wide variety of subjects and approaches to language and are, in comparison with the few reminiscences of Greek school grammars from antiquity, impressive both in quantity and quality. The extant grammatical texts, however, represent but a part of the Roman grammatical literature. We have numerous references in Roman literature to grammarians otherwise unknown to us or to grammars now lost. Furthermore, the names of the authors of many of the extant works are unknown or uncertain (cf. Kaster, 1988). In some cases a grammar is falsely attributed to an otherwise famous person known to have written an *ars grammatica* (e.g., Remmius Palaemon) or to a well-known person (e.g., St Augustine). It was common for the grammarians to copy each other extensively, often without acknowledging their sources.

The Roman Grammarians

The first extant *ars grammatica* is the work in three books by Marius Plotius Sacerdos (3rd century A.D.). The work is badly organized and apparently starts with prepositions and verbs (the manuscript is fragmentary in the beginning). After the parts of speech have been discussed, there is an extensive treatment of the ablative case and a possible seventh case in Latin. The second book is devoted to syllable quantity and phonotactic matters as well as to a classification of stems and words according to their final sounds and syllables. The third book is entirely devoted to metrics.

The African grammarian Flavius Sosipater Charisius (4th century A.D.) wrote an extensive *ars grammatica* in five books, which treats morphology (including an extensive classification of words into inflectional classes), stylistics, and metrics and which also includes a short description of the letters and their pronunciation, a list of synonyms, a list of words with different genders in Greek and Latin, and so forth. A characteristic feature of Charisius's work, and one which is unique in the *ars grammatica* tradition, is that on most controversial points he quotes extensively the views of other authors (many of them otherwise unknown). To some extent, his grammar is a compilation of early Roman grammatical literature.

Diomedes (4th or 5th century A.D.) wrote an *ars grammatica* in three volumes, which in many respects follows the arrangement of Sacerdos, except that the second book contains just a short sketch of phonology and then treats stylistics and poetical matters, including cases of correct and incorrect Latin.

The most influential Roman grammarian of the 4th century was Aelius Donatus, who wrote two grammars: *Ars minor* and *Ars major.* The *Ars minor* only treats the word classes and is written as a dialogue between the teacher who asks and the pupil who answers. The *Ars major* also includes a short phonology and aspects of correct and incorrect Latin. *Ars major* contains 21 chapters (of these topics only 7–15 are covered by the *Ars minor*).

The *ars grammatica* attributed to Marius Victorinus (4th century A.D.) illustrates another type of *ars grammatica*. Victorinus discusses in his preface what grammar should be and stresses the literary aspect of his grammar and its importance for literary studies, but limits his treatment to phonology, orthography, and metrical aspects of the syllable. A similar approach is found in the *ars* attributed to Atilius Fortunatianus (4th century A.D.?), which is mainly a book on metrics, but which in the beginning contains some short chapters on vowels, consonants, and syllables. Victorinus also wrote a short elementary *ars* in the form of questions and answers (a format that apparently started with Dontus's *Ars minor* and which became very popular in late antiquity and the Middle Ages), but which unlike Donatus' *Ars minor,* contains a lot of Greek examples.

Consentius (date uncertain) and Phocas (5th century A.D.) both limited their *artes* to the noun and the verb. Consentius also wrote a separate treatise about grammatical and stylistic errors.

The teaching of grammar beyond the elementary stage usually consisted in the teacher's reading a paragraph from a grammar and then commenting on it. Some teachers published their commentaries, thereby creating a new grammatical genre demonstrating the versatility and originality of Roman linguistics. Most influential were the commentaries on Donatus's *Ars major* by Marius Servius Honoratus (4th century A.D.) and by Pompeius (5th century A.D.). Pompeius represents a semantically oriented approach to grammatical analysis, which already can be found implicit in Servius (on whom Pompeius, to a large extent, based his work) and Phocas, and which became central in Priscian and medieval linguistics.

In contrast to the monolingual Greek grammar, Latin grammar was bilingual, covering both Latin and Greek. Many authors of an *ars grammatica* neglected Greek, however, and had no Greek examples in their texts (e.g., Donatus, Sacerdos) while others (e.g., Charisius, Diomedes, and Priscian) extensively compared their analysis of Latin with Greek and quoted Greek examples. Two authors also wrote contrastive studies. Ambrosius Theodosius Macrobius (ca. 400 A.D.) analyzed differences and similarities between the verb in Latin and Greek, focusing on verb morphology, while Dositheus (4th century A.D.) wrote a bilingual *ars grammatica*.

Priscian (*see* **Priscianus Caesariensis (d. ca. 530)**) represents both the culmination and the end of Roman linguistics. He became one of the most influential grammarians in history, and his impressive work, the *Institutiones grammaticae* in 18 books, goes far beyond what other Roman grammarians had aimed at or achieved.

The Roman *Ars Grammatica* – An Attempt at a Synopsis

The Roman grammatical tradition was a very versatile and multifaceted one characterized by continuity and development. On the one hand, there is the formally oriented elementary school grammar tradition exemplified by Donatus's two grammars and by numerous similar grammars, mostly by unknown authors. This tradition is undoubtedly very uniform, and the differences between the various grammars are relatively small. With the collapse of the Roman Empire there was a general decline in higher education and centers of learning in Western Europe. Donatus's elementary textbooks or Christianized versions of them became the basis for elementary teaching of Latin in Western Europe (Holtz, 1981).

In a situation where the language of the pupils was either very divergent from the norms of classical Latin or another language altogether, these books may also have been the most suitable ones available. But in the classical Roman educational system, where the language of the pupils was quite close to the written language and where the main purpose of grammar teaching was to help the pupils to acquire a necessary metalanguage for reading and analyzing poetical literary texts, grammars like those of Victorinus and Fortunatianus must have been much more instrumental.

Other grammars (e.g., those of Sacerdos, Charisius, Diomedes, and Priscian) and the commentaries on Donatus cover a number of different genres, topics, and theoretical approaches. Usually they include, besides the basic morphological part, a treatment of metrical matters, phonology (especially syllable quantity), orthography, and a comparison of Latin and Greek.

A characteristic aspect of the Roman grammatical tradition is the extensive treatment of stylistic matters, including statements concerning 'correct' and 'incorrect' Latin. Much space was devoted to establishing principles for correctness of language and to asking whether structural uniformity of paradigms, language usage, and/or the authority of the best authors should be the decisive criterion in cases of doubt.

While in the beginning the grammarians used a mixture of semantic and formal morphological criteria in their analysis and classification of Latin morphology, Donatus established a purely nonsemantic approach, which became dominant in the elementary *ars grammatica*. Among other grammarians, however, a more semantically oriented approach emerged, culminating in Pompeius, Phocas, and Priscian, who laid the foundation for the philosophical approach to language analysis in the Middle Ages.

Most authors had their favorite theme(s); for instance, the *Instituta artium* spuriously attributed to Probus concentrates on the comparison of adjectives. Another popular topic was the analysis of the Latin case system. Not only had Latin one more case than Greek (namely, the ablative), but also the semantic and partly morphological heterogeneity of the ablative (originating from three Indo-European cases, viz. instrumental, locative, and ablative) led some grammarians (e.g., Sacerdos and Diomedes) to discuss the position of the ablative and to ask whether the ablative was, in effect, one or two cases.

While the phonology (i.e., letters and their pronunciation and syllable quantity) and the morphology with its numerous paradigms and lists of examples are based in most instances on data without sources and probably to a large extent on the author's introspection (Priscian is an exception), stylistic and metrical matters are usually well-documented with quotations from the main Latin poets (very rarely prose writers), especially Virgil and Horace.

The most important aspect of the Roman *ars grammatica* is that it formed the grammatical metalanguage and, above all, the structural arrangement for elementary and advanced grammars and textbooks for language teaching in Western Europe for more than 1000 years. Even today many grammars have clear echoes of Donatus.

Romance Languages

R Wright, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

The Romance languages are those that have developed from the spoken Latin of the early Middle Ages. In this sense one can claim that Latin is not dead; about a quarter of the world's population still speak it; but it has acquired several new geographically based names (Spanish, Portuguese, French, Italian, Romanian, Catalan, Occitan, Sardinian, Galician, Rhaeto-romanic, here listed roughly in descending order of number of speakers). These are for political reasons considered to be separate 'Romance' languages, but there is still essentially one dialect continuum overlaid by the several artificially extended standards. Apart perhaps from Romanian, the location and history of whose earliest speakers is still controversial, the definitive divergence into separately identifiable languages should be dated to no earlier than the 9th century, and in several cases later.

Reconstruction

There are two main kinds of evidence for the Romance (spoken Latin) that existed before the separate languages diverged: surviving written texts and the results of 'reconstruction.' Hall and others have reconstructed a hypothetical 'Proto-Romance' on the basis of the later Romance languages; features they have in common are taken to have existed in their ancestors. As compared with 'classical' Latin, this Proto-Romance contains, for example, no neuter nouns, no ablative cases, no datives and genitives outside pronouns, no synthetic passives or futures, no adverbs in *-iter*, no phonemic length distinctions in vowels, no originally final consonants other than alveolars, and no velar consonants before front vowels other than those that were originally labiovelar. On the other hand, the evidence of modern Romance languages suggests that their base included extended uses of prepositions (particularly *ad* and *de* to replace inflectional nominal suffixes); analytic passives with auxiliary *esse* + tense-indeterminate participles; extended use of grammatically reflexive *se* with passive meaning; analytic futures (and 'conditionals') formed with the infinitive + *habeo*; new analytic perfects (including future perfects and pluperfects) formed with activized participles + *habeo*; extensive use of *ille* and *ipse* with the functions of the definite article; many diminutives in *-iculum* and other affixed forms (such as *adiutare*, rather than *iuvare*, as the base of Port *ajudar*, Sp *ayudar*, Cat *ajudar*, Fre *aider*, Italian *aiutare*, Romanian *ajuta*, etc.); the use of preposed *magis* or *plus* instead of comparative *-ior*; palatal affricates and semivowels; and much new vocabulary from, in particular, Germanic sources.

Texts

This reconstructed language is not very much like that of the surviving written texts of the time. Janson described reconstruction and textual analysis as two different key-holes through which one can look into the same large room, for the rules of correct writing did not change, and 'mistakes' are rarely attested. Most texts were written on perishable wax tablets or papyruses; the extant versions are usually later

The most important aspect of the Roman *ars grammatica* is that it formed the grammatical metalanguage and, above all, the structural arrangement for elementary and advanced grammars and textbooks for language teaching in Western Europe for more than 1000 years. Even today many grammars have clear echoes of Donatus.

The Romance languages are those that have developed from the spoken Latin of the early Middle Ages. In this sense one can claim that Latin is not dead; about a quarter of the world's population still speak it; but it has acquired several new geographically based names (Spanish, Portuguese, French, Italian, Romanian, Catalan, Occitan, Sardinian, Galician, Rhaeto-romanic, here listed roughly in descending order of number of speakers). These are for political reasons considered to be separate 'Romance' languages, but there is still essentially one dialect continuum overlaid by the several artificially extended standards. Apart perhaps from Romanian, the location and history of whose earliest speakers is still controversial, the definitive divergence into separately identifiable languages should be dated to no earlier than the 9th century, and in several cases later.

Reconstruction

There are two main kinds of evidence for the Romance (spoken Latin) that existed before the separate languages diverged: surviving written texts and the results of 'reconstruction.' Hall and others have reconstructed a hypothetical 'Proto-Romance' on the basis of the later Romance languages; features they have in common are taken to have existed in their ancestors. As compared with 'classical' Latin, this Proto-Romance contains, for example, no neuter nouns, no ablative cases, no datives and genitives outside pronouns, no synthetic passives or futures, no adverbs in *-iter*, no phonemic length distinctions in vowels, no originally final consonants other than alveolars, and no velar consonants before front vowels other than those that were originally labiovelar. On the other hand, the evidence of modern Romance languages suggests that their base included extended uses of prepositions (particularly *ad* and *de* to replace inflectional nominal suffixes); analytic passives with auxiliary *esse* + tense-indeterminate participles; extended use of grammatically reflexive *se* with passive meaning; analytic futures (and 'conditionals') formed with the infinitive + *habeo*; new analytic perfects (including future perfects and pluperfects) formed with activized participles + *habeo*; extensive use of *ille* and *ipse* with the functions of the definite article; many diminutives in *-iculum* and other affixed forms (such as *adiutare*, rather than *iuvare*, as the base of Port *ajudar*, Sp *ayudar*, Cat *ajudar*, Fre *aider*, Italian *aiutare*, Romanian *ajuta*, etc.); the use of preposed *magis* or *plus* instead of comparative *-ior*; palatal affricates and semivowels; and much new vocabulary from, in particular, Germanic sources.

Texts

This reconstructed language is not very much like that of the surviving written texts of the time. Janson described reconstruction and textual analysis as two different key-holes through which one can look into the same large room, for the rules of correct writing did not change, and 'mistakes' are rarely attested. Most texts were written on perishable wax tablets or papyruses; the extant versions are usually later

manuscript copies prepared by scribes who had specific instructions to 'correct' their originals according to the arcane and eventually archaic rigidities of the Imperial grammarians. Texts without such distortions are few; Adams has published some letters and drafts, and Våånånen's study of the Pompeii *Graffiti* revolutionized the discipline by showing how 'incorrectly' nonscholars wrote in 79 A.D. Even these texts, however, are obviously not phonetic transcriptions of actual speech. From painstaking statistical analyses of surviving inscriptions (mostly on tombstones), whose textual details cannot be 'corrected,' Herman has concluded that Imperial spoken Latin was evolving but also converging, with new features starting in one place becoming eventually attested anywhere. Some further progress is made by studying borrowings from spoken Latin into, for example, Irish, Welsh, Berber, Albanian, and Greek.

Divergence

Wide variation arose, but this need not imply mutual unintelligibility. Many historians, textual critics, philologists, sociolinguists, and historical linguists currently view early Medieval Romance Europe as a single lively speech community, where almost everyone could understand old-fashioned written texts when read aloud (McKitterick, 1990, Wright, 1991). These were not 'Dark' Ages. Early Medieval speakers rarely made metalinguistic distinctions that we take for granted now, neither diatopic (between French, Spanish, etc.) nor diastratic (between Romance and Medieval Latin). The latter distinction was probably imported from Germanic-speaking areas, where vernacular Germanic and official Latin *grammatica* were unrelated and self-evidently different languages; conscious distinctions between separate Romance languages became widespread only after the fashion for inventing distinctive writing systems in different areas, which began experimentally in 9th-century eastern France but generalized only in the 12th and 13th centuries. Indeed, to some extent the speech of the central Romance area is still mutually intelligible, given goodwill and clarity from those in the conversation; peripheral languages, such as Romanian, Portuguese, and French, are rarely intelligible elsewhere.

Romani

Y Matras, University of Manchester, Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

Definitions

Romani (referred to by its speakers as *řomani čhib* 'the Romani language' or *řomanes* 'in a Romani way') is the only Indo-Aryan language spoken exclusively in Europe, as well as by emigrant populations in the Americas and Australia. The language is often referred to as 'Gypsy'; it is important, however, to distinguish between Romani, which is the fully fledged, everyday family and community language spoken by the people who call themselves *Řom*, and secret or in-group vocabularies employed in various parts of the world, including in Europe, by other populations of peripatetics or so-called service-nomads. There is nevertheless some interface between the two phenomena: in some regions of Europe, especially the western margins (Britain, the Iberian peninsula, Scandinavia), Romani-speaking communities have given up their language in favor of the majority language but have retained Romani-derived vocabulary as an in-group code. Such codes, for instance *Angloromani* (Britain), *Caló* (Spain), or *Rommani* (Scandinavia) are usually referred to as *Para-Romani* varieties.

In the absence of reliable census figures, the total population of Romani speakers can only be estimated, at anywhere upwards of 3.5 million. The largest concentrations of Romani speakers are in southeastern and central Europe, especially Macedonia, Bulgaria, Romania, and Slovakia. Romani has traditionally been an oral language, and in more traditional communities there is even opposition to codification attempts or other public use of the language, which is viewed as having protective functions. The overwhelming trend, however, since the early 1990s has been toward codification of the various dialects at local or regional levels. The language is now used in local media, on numerous Internet sites, as a medium of correspondence (especially electronic), and in some countries even as a medium of school instruction.

History

The earliest attestation of Romani is from 1542, in Western Europe. Our understanding of the language's historical development is therefore dependent on reconstruction and comparison with other Indo-Aryan idioms as well as with the contact languages. In phonology, Romani shares a number of ancient isoglosses with the Central branch of Indo-Aryan, most notably the realization of Old Indo-Aryan *r̥* as *u* or *i* (Sanskrit *śr̥ṇ-* Romani *šun-* 'to hear') and of *kṣ-* as *kh* (Sanskrit *akṣi* Romani *j-akh* 'eye'). In contrast, however, to the other Central languages, Romani preserves a number of dental clusters (Romani *trin* 'three', *phral* 'brother'; cf. Hindi *tīn*, *bhāi*). This led Turner (1926) to assume a Central origin of Romani, with subsequent migration to the Northwest before the reduction of the relevant clusters took place. A northwestern migration is of course well in line with an utlimate migration out of India and on towards Europe. Further support for Turner's theory comes from the domain of verb morphology, where Romani follows the exact same pattern as Northwestern languages such as Kashmiri or Shina in its renewal of the past-tense conjugation through the adoption of oblique enclitic pronouns as person markers (*kerdo* 'done' + *me* 'me' > *kerdjom* 'I did'). Proto- or pre-European Romani was thus a kind of Indian hybrid: a central Indic dialect that had undergone partial convergence with northern Indic languages. Although the retention of dental clusters would suggest a break with the Central languages during the transition period from Old to Middle Indo-Aryan, the overall morphology of Romani indicates that the language participated in some of the significant developments leading toward the emergence of New Indo-Aryan (such as the reduction of the nominal case system to a two-way opposition, nominative vs. oblique, and grammaticalisation of new, postposed case markers). It would appear therefore that Proto-Romani did not leave the Indian subcontinent until late in the second half of the first millennium CE. Romani is among the most conservative New Indo-Aryan languages in retaining a full consonantal present conjugation, as well as consonantal oblique nominal case endings. Typical phonological developments that characterize Romani among the Indo-Aryan languages are the devoicing of aspirates *bh, dh, gh* to *ph, th, kh*, the shift of medial *d, t* to *l*, of short *a* to *e*, of inflectional *-a* to *-o*, of initial *kh* to *x*, and of the retroflexes *ḍ, ṭ, ḍḍ, ṭṭ, ḍh* etc. to *r* and *ř*.

The subsequent development of the language was strongly influenced by its contact languages. Romani borrowed lexicon and some grammatical vocabulary from Iranian languages and Armenian. The heaviest impact on Early Romani (European Romani, between the 10th and 13th centuries C.E.) was of Byzantine Greek. Apart from numerous lexical loans, phonemes, and grammatical vocabulary, Romani adopted Greek inflectional morphology in nouns and verbs, which remain productive with loan vocabulary from subsequent European contact languages (see below). Greek

also had a strong impact on the syntax of Romani, triggering among other things a shift to VO word order and the emergence of a preposed definite article.

The sound system

Romani dialects generally preserve an aspirated set of voiceless stops *ph, th, kh* as well as *čh*, alongside *p, t, k, č* and *b, d, g, dž*. Nasals are *m* and *n*, fricatives are *f, v, x, h, s, z, š,* and in some dialects also *ž*, and there is an affricate *c* [ts]. All dialects have *l* and *r*, and some also retain *ř*, which is realized as either a uvular [ʀ], a long trill [rr], or in some dialects a retroflex [ɽ, ɻ]. Palatalization of consonants, either distinctive or nondistinctive, is common in the Romani dialects of eastern and southeastern Europe. The vowel system consists of *a, e, i, o, u*, with addition in some dialects of a central vowel *ə* or *ɨ*. Western European dialects of Romani tend to show vowel length distinctions. The phoneme inventory of individual dialects usually accommodates additional phonemes from the respective contact languages in lexical loans. Conservative stress in Romani is on the final inflectional segment of the word, though a number of affixes remain unstressed, among them the vocative ending, agglutinative (Layer II) case endings (see below), and the remoteness tense marker. Dialects in Western and Central Europe often show a shift of stress to earlier positions in the word.

Morphology

Nominal forms

Romani nominal morphology is inflectional, with some agglutination. There are two genders,masculine and feminine, and two numbers, singular and plural. Mass nouns often allow omission of overt plural marking. The principal inflectional alternation in the noun is between two 'basic' or Layer I cases, nominative and oblique, in the singular and plural. The different patterns of alternation constitute declension classes. Romani declension classes are sensitive to gender, to the phonological shape of the stem, and to etymology, with European loans taking Greek-derived case endings. Basic inherited declension classes are presented in Table 1.

Individual dialects show various patterns of analogies among the different classes. Loan declension classes typically have Greek-derived inflection endings *-os*, *-o*, *-is*, or *-us* (masculine) and *-a* (feminine), with a variety of plural endings such as *-i*, *-e*, *-ides*, *-uri* and more. The oblique stem serves as the base for further (Layer II) agglutinative case formation, with the endings *-te/-de* (locative and prepositional), *-ke/-ge* (dative), *-tar/-dar* (ablative), *-sa(r)* (instrumental and comitative), and *-ker-/-ger-* (genitive). As in other Indo-Aryan languages, the genitive agrees with the head noun (*čhav-es-ker-o phral* 'the boy's brother,' *čhav-es-ker-i phen* 'the boy's sister'). The oblique without a Layer II extension serves as the case of the direct object ('accusative') with animate nouns.

Table 1 Basic ikeoclitic declension classes

	Sg. nominative	*Sg. oblique*	*Pl. nominative*	*Pl. oblique*
Masculines in $-o$	*čhav-o* 'boy'	*čhav-es-*	*čhav-e*	*čhav-en-*
Masculines in $-\phi$	*phral* 'brother'	*phral-es-*	*phral-a*	*phral-en*
Feminines in $-i$	*řomn-i* 'woman'	*řomn-ja-*	*řomn-ja*	*řomn-jen-*
Feminines in $-\phi$	*phen* 'sister'	*phen-a-*	*phen-a*	*phen-en-*

Adjectives usually take vowel endings that agree with the vocalic case-endings of the noun (*mir-o dad* 'my father,' *mir-i daj* 'my mother'). Demonstratives usually show a four-term system, encoding both proximity/remoteness (or, rather, presence in the situation vs. the discourse context), and general/specific (disambiguation), e.g., *adava, akava, odova, okova*. Interrogatives are cognate with other Indo-Aryan languages (*kon* 'who,' *kaj* 'where'), with *so* 'what' serving as the base for several derived forms (*savo* 'which,' *soske* 'why,' *sode* 'how many,' etc.). Indefinite markers are often borrowed from the respective contact languages.

Verbs

Valency is a central feature of Romani verb morphology. It is expressed through direct affixation to the verb root. The productivity, however, of individual valency markers varies among the dialects. Typical valency-increasing markers are *-av-*, *-ar-*, *-ker-*, and valency-decreasing markers are *-jov-* and *-áv-*. They derive verbs from other verb roots, as well as from nouns and adjectives. Borrowed verbs carry loan verb extension or adaptation markers, based on Greek-derived tense/aspect affixes such as *-iz-*, *-in-*, *-is-*, sometimes in combination with valency affixes (e.g., *-is-ar-*, *-is-ker-*).

The default stem (root with derivation marker) serves as a non-perfective aspect. The plain form of the nonperfective serves as a present/subjunctive. A tense/modality extension *-a* marks the present/indicative, the future, or conditional, depending on the dialect. A perfective aspect (also 'aorist' or 'simple past') is formed by attaching a perfective extension (derived from the Middle Indo-Aryan participle extension *-t-*) to the root of the verb

(e.g. *ker-d*-'did'). The choice of perfective extension depends on the numerous perfective classes, which are sensitive to the root phonology as well as to valency and semantics.

There are two person conjugations: The present conjugation (1sg *-av*, 2sg *-es*, 3sg *-el*, 1pl *-as*, 2/3pl *-en*) continues the Middle Indo-Aryan set of present concord markers. There are two inflection classes in the present (nonperfective), distinguishing vocalic and consonantal roots (*xa-s* 'you eat,' *kam-es* 'you-want'). The perfective conjugation, which follows the perfective extension, derives from late Middle Indo-Aryan enclitic pronouns (1sg *-om*, 2sg *-al/an*, 3sg *-as*, 1pl *-am*, 2pl *-an/-en*, 3pl *-e*).

Both the present and the perfective may be extended by a remoteness marker *-as/-ahi/-ys/-s* that is external to the subject concord marker, indicating the imperfect/habitual/conditional (with the present) or the pluperfect/counterfactual (with the perfective).

Syntax

Romani stands out among the Indic languages through its Europeanized, specifically Balkanized syntax. Word order is VO, with variation between thetic (continuative) VS and categorical (contrastive) SV. Local relations are indicated by prepositions. Adjectives and determiners generally precede the noun, as does the definite article (which agrees with the noun in gender, number, and case). Relative clauses are postposed, and often introduced by a universal relativizer *kaj* < 'where.' Clauses are generally finite. Adverbial clauses are introduced by conjunctions, usually derived from interrogatives. Romani distinguishes between factual and nonfactual complex clauses. Modal, manipulation, and purpose clauses are introduced by a nonfactual conjunction *te*, as are conditional clauses. Epistemic complements are introduced by *kaj*, which is often replaced by a borrowing from the respective contact language.

Dialect diversity

Dialect differentiation in Romani appears to have emerged largely in situ, following the dispersal of groups from the Balkans into western and northern Europe, from around the 14th century onward, and their settlement in their present locations, during the 16th-17th centuries. There are two major diffusion centers of innovations: in the southeast, especially the northern Balkans, and in western-central Europe, especially Germany. Typical of the western-northern dialects are prothesis of *j-*, simplification of *ndř* to *r*, loss of adjectival past-tense in intransitives (*gelo*, *geli* > *geljas* 'he/she went'), and retention of *-n* in the abstract nominalizer *-ipen/-iben*. In the central regions, *s* in grammatical paradigms is often replaced by *h*. Individual regions show distinct developments in morphological paradigms, especially demonstratives, 2/3pl perfective concord markers, and loan verb markers. Especially these latter isoglosses justify the current classification into the following dialect groups: Balkan (with a subgroup 'Black Sea Coast'), Vlax (Transylvannia and adjoining regions), Central, Northeast (Baltic-Northrussian), and Northwest (German-Scandinavian).

Romania: Language Situation

D R Ladd, The University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

The central feature of the language situation in Romania, as in several other countries of Central and Eastern Europe, such as Bulgaria and Poland, is the existence of stable minority-language communities within the geographical confines of what would otherwise be a relatively homogeneous nation state. Any description of the situation must take into account the historical tensions among the various ethnic or national groups, the post-war Communist government's efforts to create a strong centralized administration, and the still uncertain political future.

The broad outlines of the situation are straightforward. The only official language is Romanian, spoken as a first language by approximately 88% of the

(e.g. *ker-d*-'did'). The choice of perfective extension depends on the numerous perfective classes, which are sensitive to the root phonology as well as to valency and semantics.

Romania: Language Situation

D R Ladd, The University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

The central feature of the language situation in Romania, as in several other countries of Central and Eastern Europe, such as Bulgaria and Poland, is the existence of stable minority-language communities within the geographical confines of what would otherwise be a relatively homogeneous nation state. Any description of the situation must take into account the historical tensions among the various ethnic or national groups, the post-war Communist government's efforts to create a strong centralized administration, and the still uncertain political future.

The broad outlines of the situation are straightforward. The only official language is Romanian, spoken as a first language by approximately 88% of the

population (1977 census figures). The standard language is essentially uniform throughout the country, having been established as a standard only in the 19th century, though there is a fair amount of variation in nonstandard rural speech. Standard Romanian is the language of administration and virtually all higher education. During the Communist period, members of the national minorities (referred to by the Romanian phrase *popoarele conlocuitoare*, lit. 'co-inhabiting peoples') were expected to learn Romanian in school, and virtually all did so. However, there were provisions for the extensive use of minority languages in primary and secondary education, publishing, broadcasting, and the arts – provisions comparable to those made by other Communist governments in post-World War II Eastern Europe. Wherever the ethnic composition of the population warranted it, newspapers and books were published in minority languages, and schools and state-supported theatres in minority languages were established.

Romania's current territory is traditionally divided into three provinces: Wallachia (Rom. *Ţara Românească*) to the south, Moldavia (Rom. *Moldova*) to the east, and Transylvania (Rom. *Transilvania* or *Ardeal*, Hung. *Erdély*, Ger. *Siebenbürgen*) to the north and west on the continental side of the Carpathian Mountains. The two main groups of minority language speakers, Hungarians and Germans, are concentrated in Transylvania, which has a long history as a semi-independent feudal state. As early as the 14th century, the Transylvanian nobility was almost exclusively Hungarian, whereas the military and merchant classes in the developing cities were in many cases German. The peasantry was by no means entirely Romanian, but most Romanians were peasants. Romanian nationalist movements were active during the late 18th and 19th centuries, when Transylvania was part of the Austro-Hungarian Empire, and in 1920, the province was awarded to Romania under the Treaty of Trianon. The catalogue of wrongs arising from this complex history is both substantial and tended carefully by all the groups concerned.

There are Hungarians living throughout Transylvania. They represent some 8% of the population of Romania as whole, but in certain areas of the province, they constitute a substantial majority. They do not regard themselves as Romanian. Hungarian remains in active use almost everywhere – in the officially supported contexts discussed above, and in shops and on unofficial (but not official) signs. The Germans, by contrast, are restricted to scattered settlements in and around the cities in the south of the province (e.g., Sibiu, Ger. *Hermannstadt*) and various rural communities, especially in the Banat (the far western area around Timzişoara). At the time of the 1977 census, the Germans made up 1.2% of the population of Romania as a whole, but under the terms of an agreement with West Germany, a substantial proportion of the German population emigrated during the 1980s, and it is not clear whether the German-speaking communities will survive for much longer.

Throughout the country, there are small populations of speakers of other languages, including Serbian, Ukrainian, and Romany (Romani). Together, they constituted 2.8% of the population in 1977. In addition, there is a large population of Romanian speakers in the former Soviet Republic of Moldavia (the eastern half of the historical province of Moldavia), now generally known in English by its Romanian name Moldova. During the Soviet period, 'Moldavian' was written in the Cyrillic alphabet and treated as a separate language. The orthography has since reverted to that of standard Romanian.

Toward the end of the Ceauşescu regime, many of the provisions for minority languages were dismantled, in what members of the minority communities saw as deliberate Romanianization. This perception may be exaggerated: Ceauşescu's policies (in particular, the destruction of villages and the 'systematization' of their displaced inhabitants in 'agro-industrial complexes') often affected ethnic Romanians as well. Nevertheless, the Romanian nationalist bent to Ceauşescu's policies was unmistakable, and nationalism remains a powerful force in post-Communist politics. It is difficult to predict how it will affect the language situation in the coming decades.

Romanian

J Augerot, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

The Romanian (alternatively spelled Rumanian, Roumanian) language is a member of the Romance languages and is a continuation of Eastern Latin, spoken in the Roman province of Dacia and surrounding areas which were colonized by the Romans led by the emperor Trajan from 106 A.D.

The Eastern Latin spoken in this area by Roman soldiers and colonists along with presumably assimilated local tribes underwent numerous influences after the Roman legions abandoned the northernmost areas in 271 A.D. The first major influence was undoubtedly provided by the indigenous Dacian–Thracian–Illyrian inhabitants of the area, although only a few undisputed words from that source remain. A. Rosetti mentions some 88 Indo-European but pre-Latin terms whose existence in both Romanian and Albanian suggests a substratum as the source for these words in both languages, e.g., *barză* 'stork,' *bucurie* 'happiness,' *mănz* 'colt,' *mos* 'old man'; cf. Albanian *bardhë* 'white (FEM),' *bukuri* 'beauty,' *mëz* 'colt,' *moshë* '(old) age.' It is likely that some of Romanian's morphosyntactic structure, especially that shared with the non-Romance Balkan languages, also comes from this pre-Latin substratum, but the complete lack of textual evidence leaves these possibilities in the realm of speculation.

The longest and most consistent influence was that of the Slavs, who began to migrate across this territory to the south as early as 400 A.D. and who remain neighbors on three sides of present-day Romania. Several other migrations of peoples crossed the territory of today's Romania between the departure of the Roman legions and the appearance of the modern Romanian people, but little or no linguistic traces of the Goths, Huns, Gepids, Avars, *et al.* remain.

This early Romanian soon (perhaps as early as the 10th century) began to split, first into four dialects which later tended to become languages in their own right: the principal one in terms of numbers is termed Daco-Romanian, spoken primarily north of the Danube. The second largest division is called Aromanian (Macedo Romanian) and is currently spoken in pockets of southwestern Bulgaria, Macedonia, Albania, and northern Greece. The other two are quite limited in extent: Megleno Romanian is confined to an area in southeastern Macedonia and adjacent northern Greece, and Istro Romanian is limited to eight localities in Istria in modern Croatia.

Daco-Romanian is now called Romanian and is the single national language among the four with approximately 25 million speakers worldwide. It shows, in addition to the Slavic mentioned above, the influences of prolonged contact with Hungarian, Turkish, and early modern Greek. More recently, from the 19th century onwards, Romanian has been subjected to a kind of re-Latinization, both from the strong influence of French and from the international European vocabulary largely based on Latin and Italian.

The first preserved texts in Romanian date from the end of the 15th and beginning of the 16th centuries. The oldest dated text (1521) is a letter to Neacsu of Câmpulung.

Although some texts from as early as the 16th century are written in the Latin alphabet, which is the norm today, until 1860 the official alphabet was Cyrillic. Most of the letters have approximately their general European values, but there is some use of diacritics that should be noted, namely *î*, *â*, *ă*, *ţ*, *ş*. Phonetic equivalents are given where necessary in brackets in Tables 1 and 2.

Romanian symbolizes diphthongs with pairs of vowels, e.g., *iu*, *ia*, *ea*, *ua*, *oa* and *ai*, *au*, *ou*, *ui*, but one can seldom be certain from the spelling alone. See the website of the Romanian Academy Center for Artificial Intelligence for a complete inventory of multiple vowel combinations.

In contrast to the practice of some of its immediate neighbors, there is no final devoicing of consonants as

Table 1 Vowels

2. backing	mea̯sə – –	fəatə	məru – –	pəru – –
3. coalescence	masə mese	fatə fete	– – – –	– – – –
4. drop final /u, i/	– – – –	– – – –	mər mere	pər per'
normal spelling	masă mese	fată fete	măr mere	păr peri

in Bulgarian and Russian and no contrastive vowel length as in Slovak, Hungarian, and Serbian (Serbo-Croatian). Rather, Romanian forms a bridge between Serbian and Ukrainian in terms of final voiced obstruents.

The two palatal velars are disputed as separate from the dorsovelars in phonology but are clearly different on the morphophonemic plane. They represent an interesting progression from Latin 'cl' and 'gl' in words such as *cheie* 'key' and *gheaţă* 'ice.' Intentionally omitted from the chart are the palatalized variants of most consonants that, according to some analyses, occur word finally before the final (voiceless?) [i], for example in the second person singular present forms of the verb, e.g., *tu plimbi* 'you stroll,' *vezi* 'you see,' *scoli* 'you arise.'

Word stress in Romanian is basically penultimate, but only if one counts final (mostly silent and, in the case of /u/, mostly unwritten) /i/, /u/ as a syllable (the stressed vowel is given in bold type): *plecare-pleacă-plecând*, *venire-vine-venind*, *miere*. There are several exceptions to this generalization including many borrowings, e.g., through Turkish: *baklava*, *sarma*, *cafea*, and the majority of the infinitive forms, which are also stressed on the final syllable: *veni*, *citi*, *pleca*, *turna*, *putea* (historically, of course, the infinitive had a final syllable '-re'). Other exceptions include the classic Latin deviations based on heavy syllables as in *industrie* and words of specific morphological categories with stress fixed on a certain ending, such as the imperfect tense: *plecam*, *plecai*, *pleca*, etc. Note that the addition of the masculine genitive definite article /-u-lui/, the feminine definite plural article /-i-le/ or the 'multisyllabic' plural desinence /-uri/ does not cause movement of the stress: *marfă*, *mărfuri*. Thus it is not truly penultimate, only dominantly so, since one must proceed from a hypothetical base form of the word and include several classes of exceptions.

From a morphophonemic point of view, Romanian is quite complex. Space limitations will not allow a complete treatment here, but an illustration of this complexity may be seen in the singular and plural forms of words such as *masă*, *mese* 'table(s)'; *fată*, *fete* 'girl(s)'; *măr*, *mere* 'apple(s)'; *păr*, *peri* 'hair(s),'

Table 4 Verbal forms with root in /e/

present 1st sing.	văd	învăţ
present 2nd sing.	vezi	înveţi
present 3rd sing.	vede	învaţă
conjunctive 3rd sing.	să vadă	să înveţe

where only by beginning with a root with the front vowel /e/ may one predict all the forms of any one word. The three rules that are involved are illustrated in Table 3.

Rule 4 brings up some other complications such as the phonetic interpretation of consonants preceding the final 'dropped' /-i/, but it can be seen that, at least for inherited Latin vocabulary, these rules will predict the surface phonetics of many forms. Compare (given here in the normal orthography) the various forms of the verbs *a vedea* 'to see' and *a învaţa* 'to learn' with the same stressed root vowel /e/, i.e. /véd-/, /ɨnvéc-/ (see Table 4).

It can be seen that the same rules allow the derivation of all the verbal forms if we add the 'flip-flop' rule, namely, in the conjunctive-subjunctive the present third singular ending /–e/ goes to /–ə/ and vice versa. Thus *el pleacă* 'he leaves' becomes *el o să plece* while *el crede* 'he believes' becomes *el o să creadă*.

It should be noted that the stressed schwa is a feature that is often included among the features of the so-called Balkan Sprachbund. There are characteristics (merging of the genitive and dative, tendency to lose the infinitive, development of a postpositive definite article, repetition pronominally of the direct object) in several areas of the grammar that Romanian shares with languages clearly not of Romance origin such as Bulgarian, Macedonian, Albanian, and dialectal areas of Serbian and modern Greek.

Most noticeable in differentiating Romanian from the rest of Romance is the postposed definite article, which takes several forms but is basically singular *-a*, plural *-le* for feminines and singular *-l*, plural *-i* for masculines (with a special category of neuter that generally takes the masculine article in the singular and the feminine in the plural; examples in Table 5).

In the noun phrase the same definite article is attached to the first element in the phrase: *un prim pas* 'a first step,' *primul pas* 'the first step.'

Unlike the rest of Romance, although they have been whittled down to just two (plus a vocative that has almost disappeared), Romanian still maintains nominal case distinctions. Among Romanian scholars there is a tendency to name them nominative-accusative and genitive-dative after the functions of each case; see Table 6 for some examples.

Table 7 gives two verbs illustrating the basic verbal categories: *a intra* 'to enter' and *a face* 'to do.' There are, in addition to the present tense, two ways to form the future, and a variety of past tenses, including the compound past, the imperfect, the perfect and the pluperfect. Again it is instructive to consider the dropped final high vowels /u/, /i/ as morphological formants of the first and second persons singular in the present tense, both for purposes of word accent and for various other phonological alternations. The forms are given in standard orthography.

There are two general types of regular verb, one with base + back vowel and the other with base + plus front vowel, and with this information plus sets of personal endings all of the conjugations of a given verb may be produced. I chose here the verb *a intra* since it gives justification for the otherwise phantom ending /-u/ of the first person singular for a-verbs and both first singular and third plural for e-verbs (also true for i-verbs, which are not illustrated here).

All other verbal formations (except for the conjunctive-subjunctive future with *o să* plus the present, discussed above with the flip-flop rule) are synthetic, relying on either the short infinitive or the past passive participle: thus the future is *voi*, *vei*, *va*, *vom*, *veţi*, *vor* plus the infinitive (*voi intra*, *vei intra*, etc.), and the conditional is *aş*, *ai*, *ar*, *am*, *aţi*, *ar* also with the infinitive (*aş intra*, *ai intra*, etc.); while the compound past uses *am*, *ai*, *a*, *am*, *aţi*, *au* plus the past passive participial form (*am intrat*, *ai intrat*, etc.), and the past conditional also uses it after the same auxiliary as the conditional, adding the verb *fi* 'to be' (*aş fi intrat*, *ai fi intrat*, etc.). One further verb form is the past subjunctive, which does not conjugate and has a single fixed auxiliary *să fi* with the past passive participle (*să fi intrat* for all persons). There is also a 'future in the past' with *fi*.

Table 5 The definite article

Feminine	*Masculine*	*Neuter*
o doamnă *a lady*	un domn *a gentleman*	un os *a bone*
doamna doamnele	domnul domnii	osul oasele
o masă *a table*	un pom *a tree*	un lucru *a thing*

Romanian Lexicography

D Tufiş, Romanian Academy Institute for Artificial Intelligence, Bucharest, Romania

© 2006 Elsevier Ltd. All rights reserved.

Romanian lexicography has its roots in the 16th century, when the first Slavic-Romanian dictionaries where compiled, mainly to support translation of religious texts. The following century, Slavic was increasingly replaced by Latin or Romance languages (especially Italian) and by 1700 the first Romanian-Latin dictionary was compiled, *Anonymus Caransebiensis* (containing more than 5,000 entries). At first, Romanian dictionaries had circulated only as manuscripts. The first printed dictionary (four languages) appeared in 1825—*Lexiconul de la Buda* (*Lesiconul românesc-latinesc-unguresc-nemţesc*)—as a joint effort of the 'Şcoala Ardeleană' scholars. This is considered to be the starting point for the modern Romanian lexicography. In 1870 and 1879 Al. Cihac published (in French) the two volumes of his etymological dictionary *Dicţionarul etimologic dacoromân*.

The Romanian Academy, founded in April 1866, developed plans for a large dictionary of Romanian "as complete and rational as possible, to become a guide to the language" (Sala and Dănăilă, 1997). A first attempt was made in 1869, when A. T. Laurian and I. C. Massim started work on *Dicţionarul limbei române*, containing words of Latin origin, and *Glossariul*, containing words of foreign form and of uncertain origin. The two volumes, with 50 000 entries, appeared in 1873 and 1877 respectively, but were roundly criticized for excessive Latinizing of the Romanian language. However, this dictionary has the undeniable merit of being among the first dictionaries to use the principle of multiple etymologies. In 1884 editorship of the dictionary passed to B. P. Hasdeu, who produced three volumes (1887 and 1893) of the well-known *Etymologicum magnum Romaniae*, covering letters *A* and *B* (up to *bărbat*). Continuation of the task was assigned in 1897 to A. I. Philippide who, with his team, completed the dictionary up to the word *de*. When the 'Dictionary Commission' of the Romanian Academy asked for the removal of several neologisms, Phillippide gave up the task (1905) and his partial dictionary was never published.

The "*Dicţionarul limbii române/Dicţionarul Academiei*" (DLR/DA) in its present form, was started by S. Puşcariu. He and his team in Cluj worked for 43 years and published, in several fascicles, the letters *A*, *B*, *C*, *D* (up to *de*) *F*, *G*, *H*, *I*, *Î*, *J*, and *L* (up to *lojniţă*), altogether 3075 pages, containing about 60 000 words and variants. Puşcariu died in 1948, but his work was continued in Bucharest at the Institute of Linguistics, headed by Iorgu Iordan. Unfortunately, the work was interrupted in 1952 on the grounds that a general dictionary for use by ordinary people was

Romanian Lexicography

D Tufiş, Romanian Academy Institute for Artificial Intelligence, Bucharest, Romania

© 2006 Elsevier Ltd. All rights reserved.

Romanian lexicography has its roots in the 16th century, when the first Slavic-Romanian dictionaries where compiled, mainly to support translation of religious texts. The following century, Slavic was increasingly replaced by Latin or Romance languages (especially Italian) and by 1700 the first Romanian-Latin dictionary was compiled, *Anonymus Caransebiensis* (containing more than 5,000 entries). At first, Romanian dictionaries had circulated only as manuscripts. The first printed dictionary (four languages) appeared in 1825—*Lexiconul de la Buda* (*Lesiconul românesc-latinesc-unguresc-nemţesc*)—as a joint effort of the 'Şcoala Ardeleană' scholars. This is considered to be the starting point for the modern Romanian lexicography. In 1870 and 1879 Al. Cihac published (in French) the two volumes of his etymological dictionary *Dicţionarul etimologic dacoromân*.

The Romanian Academy, founded in April 1866, developed plans for a large dictionary of Romanian "as complete and rational as possible, to become a guide to the language" (Sala and Dănăilă, 1997). A first attempt was made in 1869, when A. T. Laurian and I. C. Massim started work on *Dicţionarul limbei române*, containing words of Latin origin, and *Glossariul*, containing words of foreign form and of uncertain origin. The two volumes, with 50 000 entries, appeared in 1873 and 1877 respectively, but were roundly criticized for excessive Latinizing of the Romanian language. However, this dictionary has the undeniable merit of being among the first dictionaries to use the principle of multiple etymologies. In 1884 editorship of the dictionary passed to B. P. Hasdeu, who produced three volumes (1887 and 1893) of the well-known *Etymologicum magnum Romaniae*, covering letters *A* and *B* (up to *bărbat*). Continuation of the task was assigned in 1897 to A. I. Philippide who, with his team, completed the dictionary up to the word *de*. When the 'Dictionary Commission' of the Romanian Academy asked for the removal of several neologisms, Phillippide gave up the task (1905) and his partial dictionary was never published.

The "*Dicţionarul limbii române/Dicţionarul Academiei*" (DLR/DA) in its present form, was started by S. Puşcariu. He and his team in Cluj worked for 43 years and published, in several fascicles, the letters *A*, *B*, *C*, *D* (up to *de*) *F*, *G*, *H*, *I*, *Î*, *J*, and *L* (up to *lojniţă*), altogether 3075 pages, containing about 60 000 words and variants. Puşcariu died in 1948, but his work was continued in Bucharest at the Institute of Linguistics, headed by Iorgu Iordan. Unfortunately, the work was interrupted in 1952 on the grounds that a general dictionary for use by ordinary people was

much more important. *Dicţionarul limbii române literare contemporane* (DLRLC) was intended to answer this demand and under the coordination of D. Macrea and E. Petrovici it was compiled, based on DLR/DA, and published in 1955–1957. The four volume dictionary, containing 48 000 headwords, hardly achieved its original goal of being an ordinary people's dictionary. A shorter version (all citations removed, but about 1500 new entries added) was published in 1958 as *Dicţionarul limbii române moderne* (DM).

DLRLC and DM were superseded by the *Dicţionarul explicativ al limbii române* (DEX) published in 1975, followed in 1988 by *Supliment la Dicţionarul explicativ al limbii române* (DEX-S). This dictionary, containing 56 569 entries (words and variants) is the bestselling *Dictionary of Romanian* (Vintilă-Rădulescu, 2002). The second edition (1996), republished in 1998, eliminated some inconsistencies, corrected several definitions, and added almost 9000 entries. Since August 2004 it has been publicly available on line.

Compilation of the most representative Romanian lexicographic work, represented by the DLR/DA, was resumed in 1959 at the Linguistic Institutes in Bucharest, Cluj, and Iaşi and the new series of DLR fascicles began to be published in 1965. By 2004 32 volumes had been published, listing more than 175 000 headwords and variants, with more than 625 000 meanings and about 3 200 000 citations. Between 2001 and 2004 DLR has been published in an updated and shortened version (only four volumes) as *Micul Dicţionar Academic* (MDA). To meet the size restriction, MDA discarded the citations and sources, and used a very compact encoding of lexical information.

Romanian lexicography has produced many other types of dictionaries, both monolingual and multilingual: dictionaries of neologisms, orthography, pronunciation and morphology, etymology, synonyms, antonyms, terminology, encyclopedic dictionaries, and regional and dialectal dictionaries.

Ronjat, Jules (1864–1925)

M Piot, University of Grenoble, Grenoble, France

© 2006 Elsevier Ltd. All rights reserved.

Jules Ronjat, an amateur scholar, was born in 1864 in Dauphiné (France). He was closely bound up with Provençal authors such as the Nobel Literature Prize-winner Frédéric Mistral, whom he considered the greatest authority on the Occitan language, and the other Felibrige poets, as well as his Romanist colleagues Camille Chabanneau, Emil Levy, Albert Dauzat, etc. His work was influenced by French Romanist linguists such as Gaston Paris, Father Pierre-Jean Rousselot, and Maurice Grammont. He earned his Doctorat-ès-Lettres in 1913 from the Sorbonne for his theses *Essai de syntaxe des parlers provençaux modernes* and *Le développement du langage observé chez un enfant bilingue*. In his later years he taught as a *privat-docent* at the University of Geneva.

In his reviews in the *Revue des langues romanes*, he made, as did Grammont, a critical appraisal of the linguistic geography practiced by Jules Gilliéron and his followers. As denoted by the title ('*istorique*') of his first thesis, *Essai de syntaxe des parlers provençaux modernes*, he was a champion of spelling reform

much more important. *Dicţionarul limbii române literare contemporane* (DLRLC) was intended to answer this demand and under the coordination of D. Macrea and E. Jules Ronjat, an amateur scholar, was born in 1864 in Dauphiné (France). He was closely bound up with Provençal authors such as the Nobel Literature Prize-winner Frédéric Mistral, whom he considered the greatest authority on the Occitan language, and the other Felibrige poets, as well as his Romanist colleagues Camille Chabanneau, Emil Levy, Albert Dauzat, etc. His work was influenced by French Romanist linguists such as Gaston Paris, Father Pierre-Jean Rousselot, and Maurice Grammont. He earned his Doctorat-ès-Lettres in 1913 from the Sorbonne for his theses *Essai de syntaxe des parlers provençaux modernes* and *Le développement du langage observé chez un enfant bilingue*. In his later years he taught as a *privat-docent* at the University of Geneva.

In his reviews in the *Revue des langues romanes*, he made, as did Grammont, a critical appraisal of the linguistic geography practiced by Jules Gilliéron and his followers. As denoted by the title ('*istorique*') of his first thesis, *Essai de syntaxe des parlers provençaux modernes*, he was a champion of spelling reform

and applied his principles throughout his historical syntax.

Ronjat's posthumously published four-volume historical syntax of modern Provençal dialects (the postmedieval Occitan language), a French government-sponsored publication initiated upon Antoine Meillet's recommendation, appeared under the supervision of Walter von Wartburg and Georges Millardet.

Ronjat established 19 main features of Occitan: 11 of them are phonetical, 5 morphological, 1 syntactical, and 2 lexical. On this basis, he found 7 linguistic distinctions between Occitan and Spanish, 8 with Italian, 12 with Franco-Provençal, and 16 with French. He is mainly remembered by Occitan speakers and specialists for his knowledge of all Occitan dialects. Despite the title ('Provençal' spelling), his study on the Occitan spelling applies to the analysis of Occitan pronunciation and rules.

In his second thesis on bilingual acquisition, *Le développement du langage observé chez un enfant bilingue*, undertaken due to the suggestion of Grammont, he studied the linguistic development of his bilingual child, whose mother was German, and put into practice the linguistic recommendation of Grammont: 'one language, one person.' This work is now recognized as a forerunner of contemporary research on bilingual acquisition (see, for example, the CHILD Project).

Rorty, Richard (b. 1931)

R Chatterjee, Lado International College, Silver Spring, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Richard Rorty was born October 4, 1931, in New York City. His parents were Trotskyites, and his early ideas were imbued with a Marxism that he later outgrew. Rorty is known as a pragmatist, a social commentator, and a public intellectual. One writer has chosen the term 'post-philosophical' to describe his work (Rumana). A precocious intellectual, Rorty enrolled at the University of Chicago when he was 15 and received his Ph.D. from Yale in 1956. While teaching at Wellesley and Princeton, Rorty read deeply in Carnap, Tarski, and Reichenbach. By this time, many Anglo-American philosophers were trying to read and understand the later Wittgenstein.

One of Rorty's early contributions to philosophy was an edition of essays by philosophers entitled *The linguistic turn* (1967/1992) that runs to some 400 double-columned pages. His introduction, 'Metaphysical difficulties of linguistic philosophy,' is often cited. One part of the collection is composed of essays on the thesis that philosophical questions are questions of language; another is composed of problems of ideal-language philosophy, and a third of ordinary language philosophy. Wittgenstein here is the 800-pound gorilla who couldn't be represented because his estate doesn't allow his work to be excerpted.

Representative of Rorty's mature work is his book *Philosophy and the mirror of nature* (1979). A critique of epistemology is contained in its earlier parts, of the notion inherited from the past that it is a combined development of the ideas of mind, knowledge, and of earlier philosophy itself. This critique leads in later work, such as *Truth and progress* (1998), to the characteristic doctrine of epistemological behaviorism, by which Rorty maintains that knowledge is constrained only by conversational constraints. Hence the notion of philosophy as an edifying conversation. The roots of epistemological behaviorism Rorty finds in Dewey and in Wittgenstein's critique of representation – the idea that all knowledge is found represented in the mind and is communicable from mind to mind. A further consequence is a denial of any possibility that the nature of the world constrains us to speak in certain ways. This view is reminiscent of the Nietzschean critique of language by which all language is metaphor, or 'fiction which is dependent on fictions.'

and applied his principles throughout his historical syntax.

While teaching at Wellesley and Princeton, Rorty read deeply in Carnap, Tarski, and Reichenbach. By this time, many Anglo-American philosophers were trying to read and understand the later Wittgenstein.

One of Rorty's early contributions to philosophy was an edition of essays by philosophers entitled *The linguistic turn* (1967/1992) that runs to some 400 double-columned pages. His introduction, 'Metaphysical difficulties of linguistic philosophy,' is often cited. One part of the collection is composed of essays on the thesis that philosophical questions are questions of language; another is composed of problems of ideal-language philosophy, and a third of ordinary language philosophy. Wittgenstein here is the 800-pound gorilla who couldn't be represented because his estate doesn't allow his work to be excerpted.

Representative of Rorty's mature work is his book *Philosophy and the mirror of nature* (1979). A critique of epistemology is contained in its earlier parts, of the notion inherited from the past that it is a combined development of the ideas of mind, knowledge, and of earlier philosophy itself. This critique leads in later work, such as *Truth and progress* (1998), to the characteristic doctrine of epistemological behaviorism, by which Rorty maintains that knowledge is constrained only by conversational constraints. Hence the notion of philosophy as an edifying conversation. The roots of epistemological behaviorism Rorty finds in Dewey and in Wittgenstein's critique of representation – the idea that all knowledge is found represented in the mind and is communicable from mind to mind. A further consequence is a denial of any possibility that the nature of the world constrains us to speak in certain ways. This view is reminiscent of the Nietzschean critique of language by which all language is metaphor, or 'fiction which is dependent on fictions.'

Apart from his academic activity, Rorty is engaged as a public intellectual and activist. This engagement is launched on an anti-essentialist basis. The intellectual or philosopher combines a realization of the contingency of his or her own vocabulary with the goals of reducing suffering and cruelty. The vehicle of activism is not argument, which has been rendered void by the pragmatist critique of reason, but a redescription or realignment of vocabularies in a continuing conversation. Here Rorty distinguishes himself from any radicalism that seeks to detect hitherto unknown reasons for social ills as a warrant for removing them. It is significant that most of Rorty's work is achieved in conversation with linguistic and analytic philosophers such as Wittgenstein, Quine, Sellars, Davidson, and Putnam.

Rosetti, Alexandru (1895–1990)

G Price

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 7, p. 3612, © 1994, Elsevier Ltd.

Alexandru Rosetti was born in Bucharest on October 23, 1895. After graduating in 1920 at the University of Bucharest he spent eight years in Paris where he studied under Meillet, Rousselot, and Gilliéron (*see* **Meillit, Antoine (Paul Jules) (1866–1936); Rousselot, Pierre Jean, Abbé (1846–1924); Gilliéron, Jules (1854–1926)**), among others and obtained his doctorate in 1926 for a thesis on Romanian historical phonetics. He returned to Romania in 1928 to take up a post at the University of Bucharest and in 1932 was promoted to the rank of professor. In 1938 he succeeded his former teacher, Ovid Densusianu, in the chair of the Romanian language which he was to occupy until his retirement in 1965. He maintained throughout his long life his preoccupation with phonetics, both historical and theoretical, and directed (1963–1969) the Center for Phonetic and Dialectal Research in Bucharest. His authoritative history of the Romanian language up to the 16th century, which was first published in six parts (1938–1966), was revised in one volume, taking it up to the 17th century, in 1968 (3rd edn., 1986). He also made important contributions to general linguistic theory, in particular with his book (1943) tackling the problem of defining the 'word' as a linguistic entity. He founded and edited the periodical *Bulletin linguistique* (1933–1948) and later, when existing journals were discontinued and replaced by others after the communist regime took full control of the country in 1948, edited at various times the periodicals *Studii şi cercetări lingvistice; Fonetică şi dialectologie; Revue roumaine de linguistique*; and *Cahiers de linguistique théorique et appliquée*. In the 1930s he was closely associated with King Carol II and was editorial director (1933–1945) of the Royal Foundation for Literature and Art. He succeeded, however, in coexisting with the post-1948 communist regime (he was, indeed, one of the foundation members of the Academy of the Romanian People's Republic which replaced the Romanian Academy in that year), but (unlike some others) without compromising his intellectual probity. He outlived the regime by two months and one of his last acts, after the overthrow of Nicolae Ceauşescu in December 1989, was to call for the full restoration of the Institute of Phonetics, which, like various other institutions, had been downgraded. This was done and, after his death in Bucharest on February 27, 1990, the Institute was renamed after him. (Bibliographies of his writings up to 1965, 1975, and 1980, respectively, may be found in Rosetti, 1965, 1975, 1980.)

Rousseau's *Essai sur l'origine des langues* mixes in a paradoxical way favorite topics of the 18th century and passionate – but also hesitating – intuitions about the politics of language.

The *Discours sur l'origine de l'inégalité* (1755) stresses the *embarrassments* of the question of the origin of language (*see* **Origin of Language Debate**), in a manner reminiscent of Frain du Tremblay (*Traité des langues*, 1703). Two types of conclusions were deduced: (a) this question is unsolvable and the efforts of such a great mind are typically vain (Kant; *see* **Kant, Immanuel (1724–1804)**; Nietzsche, etc); (b) there is an absolute solidarity between language and society, from which some authors will infer a sort of linguistic revelation related to a fixed political order.

According to Rousseau, the *Essai sur l'origine des langues* was 'a fragment of the *Discours sur l'inégalité*, cut out for being too long and irrelevant.' In so far as the chapters of the *Essai* dealing with the 'politics of language' offer ideas differing from the *Discours*, it has been supposed that they give an earlier, immature state of Rousseau's thinking. The contrary was also argued: the passage 'cut out' would in fact be dealing with the polemic which opposed to Rameau's theory of harmony Rousseau's ideas about the 'melodic' musicality of Italian, supposedly lost by French and more suitable to opera.

Rousseau's complexities or contradictions about language can be traced back to the picture of the origins given in the *Discours*. Speech arises amid 'singing and dancing – true children of love and leisure.' 'The best singer or dancer, the one who was the most beautiful, strong, skilful, or eloquent became the most esteemed; and it was the first step towards inequality, and towards vice at the same time.' An idealistic, sentimental conception of language is combined – at least in a dialectic tension – with a critical and materialistic approach associating language with the rise of social damage. Words appear in an 'order radically heterogeneous to the natural one,' endowed with an 'irreducible autonomy and originality.' Modern criticism has stressed the fact that the birth of a real language is described as it took place in historical times, and then seems to be separated from the very principle of 'origin' (Starobinski, 1990).
